The second link in the great telegraphic chain now in course of construction, to connect South America with Europe, has left the Thames. The steamship "Mazeppa," having the sections of submarine telegraph cable on board, started from North Woolwich on Wednesday morning, direct for the River Plate, where she will be engaged in submerging the cable between Montevideo, Maldonado and the Brazilian frontier. At Montevideo the cables about to be laid will be in connection with that already existing between Montevideo and Buenos Ayres and the Transandine lines into Valparaiso and Chili. The "Mazeppa" takes out the "cable house" for erection at the Brazilian frontier, in which the junction with the cables north into Rio de Janeiro will be effected. This cable house is a large iron structure, with internal accommodation for the engineering staff and an instrument room, the isolated and exposed position on the frontier, where it will be erected, rendering such a precaution for shelter absolutely necessary. The Montevidean and Brazilian Company, under the powers of whose exclusive concession the cables will be laid, expect the circuit to be completed to the Brazilian frontier about the end of August. The cables north to Rio de Janeiro may expected to be completed by the Autumn of this year. On Friday week the steamer "Hooper" anchored in Plymouth Sound, for the purpose of coaling before proceeding to Brazil to lay a cable between Pernambuco and Para. On Saturday the staff of the expedition, and a select circle of friends, were entertained at luncheon by Mr. Hooper, on board the steamer in Plymouth Sound. The "Hooper" sailed for Pernambuco direct on Sunday, and if all goes well will be home again in about three months. While at Plymouth she was visited by Admiral the Hon. Sir Henry Kepple, G. C. B., Port Admiral and Commander-in-Chief at Devonport, Rear Admiral Sir William King Hall, K. C. B., Admiral Superintendent of the dockyard, and others.

We learn from Valparaiso that permission has been granted to Mr. Leigh to lay a cable from a port in Atacama to another port in connection with Europe.—*The Railway News.*

NEW EXPERIMENTS IN OCEAN CABLES, ETC.

The London correspondent of the New York *Financial Chronicle*, under date of June 28th, writes:

"The experiment of light cables to the United States will soon be practically tested, arrangements to enable Mr. Highton to lay a cable across the Atlantic being in active progress. It is stated that if the experiment proves to be successful a great reduction in the charge for messages must necessarily follow.

THE directors of the Brazilian Submarine Telegraph Company made a call of £2 per share, payable on the 1st ultimo.

BY a law of the 22d of March the executive power of the United States of Colombia is authorized to grant $8,000 to keep the telegraph line in repair between Buenaventura and Bogota, especially in that part of the route from Ibague to Cartage.

A TELEGRAPH line is to be constructed between Palmyra and Popayan, United States of Colombia, on account of the Government.

THERE are 4,000 miles of telegraph now in operation in Buenos Ayres.

THE steamship "Hooper," with the submarine cable to be laid between Pernambuco and Para, arrived at Madeira on the 30th of June.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is over 8,000. It goes to every State, Territory and Province on the Continent. It has become a necessity, and is always welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, AUGUST 1, 1873.

RESPONSIBILITY OF MANAGERS.

Managers of offices should bear in mind that they re responsible for all property of the Company placed in their charge, and that the same care should be exercised in the performance of their duties as would be expected of a prudent business man in conducting his private affairs. The official blanks, counter and otherwise, are property, equally with a switch or magnet; they should not be wasted, nor allowed to be purloined. Complaint has reached us that students and others belonging to so-called telegraph institutes, are in the habit of abstracting blanks from the counters of some of the up-town offices in this city, and our advice is solicited as to the propriety of the transaction. The complaint intimates that, if these parties had the *decency* to ask for the blanks, they would not be refused.

This is all wrong. Blanks should be furnished only upon reasonable presumption that they are to be used for the purpose for which they are intended. Otherwise they should be denied. When they are stolen, proper measures should be taken to prevent a recurrence of the theft. Protect the property.

GOVERNMENT RATES.

Upon another page will be found an important correspondence between President Orton and the Postmaster-General upon the subject of the rates to be paid for telegraphic messages transmitted for the Government. Without attempting to reply to the reasons advanced why the Government should pay for telegraphic service the rates charged private citizens, the Postmaster-General re-issues the schedule of last year.

The Attorney-General combats some of the views expressed by Mr. Orton, but accepts his conclusion, viz.: that a message to be sent at the Government rate is one the tolls on which are payable out of the Treasury of the United States, or out of money payable to the Treasury.

THE SIDNEY (CAPE BRETON) CABLES.

The fourth and last cable between Sidney, Cape Breton and Placentia, Newfoundland, has been successfully laid by the steamer "Edinburgh" of the cable fleet.

FRENCH TELEGRAPHY AT THE VIENNA EXPOSITION.

A Vienna correspondent of one of the New York dailies, in describing the wonders on exhibition at the Exposition now in progress at that city, is moved to comment upon the telegraphic apparatus on view in a tone extremely deprecatory of the apparent lack of enterprise shown by Americans, and in laudation of certain apparatus in the French department. Only for one fact it would hardly be worth while to refute the erroneous conclusions of the writer, but as persons not well informed upon telegraphic subjects are liable to be misled by positive assertions, however wrong, it becomes important that the exact truth should be made manifest. This is the more necessary owing to the avidity with which prominent Government officials, thirsting for more power, seize upon such statements, probably to reproduce them as matters of fact at a favorable opportunity, in furtherance of their projects. The writer says:

"I am sorry we are not represented in telegraphic apparatus, as we have several things in America that would be worth seeing. The French telegraphic department is the best in the Exhibition, and some of the inventions are exceedingly interesting. There is a machine that prints an autographic dispatch, not chemically, like the other autographic instruments, but on white paper, with printers' ink. It cannot be described in writing, and so I will not attempt to say how it is made, except that there is synchronous action of two rollers; one may be in New York and the other in San Francisco, or in any two other places connected by a telegraph wire. A written message, a draft, a sheet of music, the portrait of a burglar, anything that can be drawn with a pen—not with a pencil—may be telegraphed from one end of the world to the other, and reproduced with printers' ink, on white paper, like that whereon the patron of *The Mail* reads this letter. Then they have a machine by which four operators can work over a single wire at once in one direction, just as one operator does with us, and by putting on four operators the other way you can make the capacity of one wire equal to that of eight by the old system. We are now using in America a system by which a wire may be operated both ways simultaneously. The French machine is exactly four times ahead of us."

The interesting character of the apparatus mentioned cannot be questioned, but their value, when compared with the improved systems of telegraph used in America, and, indeed, in every other section of the globe, may certainly be disputed with success. Nothing described in the letter is of any value. As toys, they are very pretty, but for practical uses they have been tried and discarded years ago. The machine that "prints an autographic dispatch, not chemically like the other autographic instruments, but upon white paper, with printers' ink," is that of Lenoir of Paris. In effect this is substantially the same as Bakewell's, which was brought out in 1850, the only change being that an electro-magnet with a printing pad attached to the armature is used instead of allowing the current to produce the marks upon chemically-prepared paper, a substitution which has not in any manner improved the system. Lenoir's apparatus has been thoroughly tested upon the French lines and abandoned as being of no practical value.

The machine "by which four operators can work over a single wire at once in one direction," and which is "four times ahead of us" is that of M. Meyer, which we describe in this issue of the JOURNAL. The assumption would bear greater weight were it true, but as neither four, nor any other number of operators work over a single wire at once by this system, it is evident that the correspondent errs in his statement. The best results attainable with this instrument, in the inventor's own language, has been 110 messages per hour, with four operators sending and four receiving—showing an average of 27½ messages for each operator transmitting. The average of each operator working the Duplex and the best Morse circuits in America is over 40 messages per hour, and upon one occasion as many as 146 messages were transmitted in one hour by two operators with the Duplex system, while upon the printing instruments an average of over 65 by one operator has been maintained for ten consecutive hours. So much for the superiority of the French apparatus.

It is probable that the lack of interest evinced by American electricians and inventors in the Vienna Exposition arises from distrust of the peculiar laws pertaining to patents which govern the Austrian Empire. There are scores of machines of American invention far superior to any of which we have seen a description as on view in Vienna. Essaying for prizes, and winning them too, is a characteristic of the race, and to the advantages of advertising they are not usually blind.

GYMNASTIC PERFORMANCES BY A MOUSE.

No little amusement was caused in William street, near Chambers, yesterday morning, by the performances of a mouse which came from Ann street on one of the telegraph wires, walked to about the middle of the block, where he paused and treated his constantly increasing audience to a series of performances on the slack wire, of which Blondin himself need not have been ashamed. The crowd soon became so great as to block the street, when the exhibition was brought to a close by a boot-black, who brought down the performer with a brickbat.—*N. Y. Star.*

IT now occurs so frequently that telegraphic communication is interrupted in Germany from the posts in exposed situations being blown down, and the porcelain insulators broken in the fall, even by a very moderate gale of wind, that the Director-General of the Telegraph Department has given orders to make arrangements for altering the system now in use, and letting the wires run underground. The experiment will be made, in the first instance, on the line between Berlin and Magdeburg, and, if it is found to succeed, it will be generally introduced.

The *San Diego* (Cal.) *Union* states that the Western Union Company is now engaged in the construction of a new line, following the railroad and the survey to Bakersfield, where it will terminate for a time. Between Bakersfield and Los Angeles the old line will be thoroughly repaired.

MR. J. A. HINCHMAN, for a number of years attached to the office of the Superintendent of the Metropolitan District, has resigned, to take the position of Secretary to the Assistant-Postmaster of New York City.

CORRESPONDENCE BETWEEN PRESIDENT ORTON AND THE POSTMASTER-GENERAL REGARDING RATES FOR GOVERNMENT MESSAGES.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, June 20, 1873.

Hon. JOHN A. J. CRESWELL, *Postmaster-General*, WASHINGTON, D. C.

SIR,—I have had the honor to receive your communication of the 13th instant, inviting suggestions in reference to the re-adjustment of rates at which "Telegraphic communications between the several Departments of the Government and their officers and agents" shall be transmitted, and in reply thereto, beg to say:

On the first of July, this Company will put in operation on its lines, east of the Rocky Mountains, a revised tariff, based on air-line distances, as follows:

Under 25 miles						25	cents.
Between	25	and	50	miles		30	"
"	50	"	100	"		40	"
"	100	"	200	"		50	"
"	200	"	400	"		75	"
"	400	"	600	"		$1.00	
"	600	"	800	"		1.25	
"	800	"	1000	"		1.50	
"	1000	"	1200	"		2.00	
For all distances beyond 1200 miles						2.50	

These changes effect a large reduction in the local rates throughout the Middle and Southern States. The reduction in the New England States is less, because the present rates are lower for like distances than those in other sections. It is the opinion of those of most experience in the Telegraph business in this country that a large majority of 25 cent messages are handled at a loss. Of the cost of carrying on the business—that is, the current expenses, after lines are constructed and offices equipped—60 per cent. is paid for wages, of which the wages of operators are the larger part. The cost of receiving, booking, sending to the operating room, transmitting, checking, and delivering a 25 cent. message is the same as in the case of those on which a greater charge is made. And yet it has been deemed politic to establish a 25 cent. rate, confining it, however, to stations within 25 miles. These rates are as low as private companies can afford to accept in the United States at the present time. At the higher rates which have heretofore prevailed, no company, except the Western Union, has made any profit whatever for several years past; and the Western Union, after applying its revenues to the construction of new lines, and the erection of additional wires necessary to meet the constantly increasing demands of the business, could not have made reasonable dividends, whether its property were estimated at its actual cost or at its real value. If the assumption is correct that the new rates are as low as private parties can afford to accept, it follows that when the Government, in the exercise of its authority conferred by law and the agreement of the telegraph companies, fixes a lower rate on Government messages, it imposes a hardship upon the companies.

One of the conditions of telegraphic service for the Government is that it shall have "priority over all other business." Private parties may be waiting to pay, or may have actually paid, higher rates for the use of the lines, yet it is made the duty of the companies to put aside the messages of private customers, and to send Government messages ahead of all others, and then it has been required that for the service so rendered, a sum should be accepted which was not compensation in many cases, because it did not pay the cost of rendering the service.

I submit, therefore, that the rates at which telegraphic communications between the several departments of the Government and its officers and agents shall be transmitted during the year commencing July 1, 1873, should be substantially the rates hereinbefore named, and which will take effect on that day. The present rate between Washington and New York is 40 cents; under the scale now in operation it would be 75 cents; under the new scale it would be 50 cents. But, it is not intended to advance the present rate, even if the competition out of which it arose should be discontinued. The Government rate between Washington and New York is 25 cents. I have already expressed the opinion that it does not pay the cost of doing the business. I suggest, then, that even if you shall decide to continue the present 250 mile scale, that the rate for the first 250 miles be increased from 25 to 40 cents. As an offset to this increase I should be willing that no charge should be made beyond 10 circuits of 250 miles each. That is to say: a Government message of 25 words shall not be charged more than $2.50 for transmission over the lines of any one telegraph company within the United States.

I make no suggestion concerning the rates for Signal Service Messages and Reports, being of the opinion that the rates which the Postmaster-General is authorized to fix, must be uniform in their application to Government messages without regard to the matters to which such messages relate, or to the Bureau or Department of the Government for which they are transmitted.

In this connection permit me to call your attention to the following case which recently came before me:

A District Attorney of the United States applied for an order directing that his messages relating to his official business be received and payment accepted at Government rates. I expressed the opinion that the rates which the Postmaster-General is authorized to fix are applicable only to communications exchanged "between the several Departments of the Government and their officers and agents," and not upon communications between such agents directly. But as such a construction, if accepted, would be difficult to enforce, I suggested that the test applicable to all cases where claim is made that messages should be sent at Government rates should be this: if the tolls are to become a charge against the United States, payable out of the Treasury, then the message should be sent at Government rates; but if, as in the case of a U. S. Marshal or Attorney, the disbursements for telegraphing are payable out of official fees or commissions, or from the proceeds of penalties or forfeitures, then the Government rates should not apply. I should be glad to receive a statement of your views on this point.

Very respectfully,
Your obedient servant,
(Signed) WILLIAM ORTON,
President.

DEPARTMENT OF JUSTICE,
July 10th, 1873.

SIR: I have the honor to acknowledge the receipt of your letter of the 26th ultimo, asking for my opinion upon case presented as follows:

The Honorable William Orton, President of the Western Union Telegraph Company, in a letter addressed to you, under date of 20th June instant, expressed the opinion that the Government rates should not apply to telegraphic communications on official business transmitted directly between officers or agents of the Government; and you quote from his letter as follows:—"A district attorney of the United States applied for an order directing that his messages relating to his official business be received and payment accepted at Goverment rates. I expressed the opinion that the rates which the Postmaster-General is authorized to fix, are applicable only to communication exchanged between the several Departments of the Government and their officers and agents, and not upon communications between such agents directly. But as such a construction, if accepted, would be difficult to enforce, I suggested that the test applicable to all cases where claim is made that messages should be sent at Government rates should be this: If the tolls are to become a charge against the United States, payable out of the Treasury, then the message should be sent at Government rates; but if, as in the case of a U. S. Marshal or Attorney, the disbursements for telegraphing are payable out of official fees or commissions, or from the proceeds of penalties or forfeitures, then the Government rates should not apply."

I do not agree to the applicability of the test proposed by Mr. Orton, or to his conclusions upon the point presented. Certain rights and privileges as to the public lands and otherwise are granted by the Act of July 24, 1866, entitled, "An Act to aid in the construction of telegraph lines, and to secure to the Government the use of the same for postal, military, and other purposes" (14 U. S. Stat., 221,) to such telegraph companies as shall file with the Postmaster-General a written acceptance of the obligations and restrictions thereby imposed. Section 2 of said Act is as follows: "That telegraphic communications between the several departments of the Government of the United States and their officers and agents shall, in their transmission over the lines of any of said companies, have priority over all other business, and shall be sent at rates to be annually fixed by the Postmaster-General."

Manifestly the object of this section, as indicated by the title of the Act, was to require such companies as availed themselves of its benefits, to transact the business of the Government at rates to be annually fixed by the Postmaster-General. I think that the word "between" in said section should be taken distributively as applying to communications between, first, one department and another; second, a department and its officers and agents; third, a department and the officers and agents of another department; fourth, the officers and agents of the same department; and fifth, the officers and agents of one, and those of another department. This construction is, in my judgment, in conformity with the reason of the statute.

Mr. Orton seems to think that district attorneys and marshals are entitled to the fees which they receive, but they are required by the third section of the Act of February 26, 1853, (10 U. S. Stat., 161,) to account for every dollar thereof and pay over the same into the Treasury of the United States, retaining therefrom a compensation fixed by law for their services. To compel them, therefore, to pay higher than other officers for official telegraphing, would be, to that extent, in many cases as much of a loss to the Treasury as though the money had been directly appropriated therefrom for that purpose.

Mr. Orton's test is wholly inadmissible on account of its want of uniformity. Why should an officer whose maximum compensation is three thousand dollars, to be made out of fees, pay for Government telegraphing higher rates than any other officer for similar telegraphing, whose salary of three thousand dollars is paid directly out of the Treasury?

Mr. Orton gives an unreasonably narrow construction to the second section of said Act. Why should a telegraphic message from the Attorney-

Digitized by Google

General to a district attorney be sent for twenty-five cents, when the district attorney, for telegraphing the same number of words the same distance to the marshal of his district, and upon the same business, is compelled to pay one dollar? Both messages may be of equal importance and both upon Government business. Can any good reason be given why a collector of Internal Revenue, in telegraphing to a district attorney upon the business of his office, should pay a higher rate than the Commissioner of Internal Revenue is required to pay for a like telegram to the collector? Departments, as far as their administrative acts are concerned, are nothing but officers and agents of the Government.

Clearly to my mind, the intent of Congress was that telegraph companies operating under the Act of July 24, 1866, should transact the business of the Government at rates fixed by the Postmaster-General, and it is of minor importance as to who sends or receives the telegrams. My opinion, therefore, is that the Departments, their officers and agents, may interchangeably telegraph each other as hereinbefore stated, upon official business, subject only to the limitation that the telegraphing must be in cases where the rates are payable out of public moneys, or are to be accounted for to the Government by the officer making the expenditures.

Very respectfully,

(Signed) GEO. H. WILLIAMS,
Attorney-General.

Hon. JNO. A. J. CRESSWELL,
Postmaster-General.

RATES OF PAY FOR COMMUNICATIONS BY TELEGRAPH, 1873-'74.

POST-OFFICE DEPARTMENT,
June 28, 1873.

WHEREAS, by the Act of Congress approved July twenty-fourth, A. D. eighteen hundred and sixty-six, entitled "An Act to aid in the construction of telegraph lines, and to secure to the Government the use of the same for postal, military and other purposes," in section second it is enacted—"That telegraphic communications between the several Departments of the Government of the United States and their officers and agents shall, in their transmission over the lines of said companies, have priority over all other business, and shall be sent at rates to be annually fixed by the Postmaster-General;"

Now, therefore, in pursuance and by virtue of the authority on me by said Act conferred, I, J. A. J. Creswell, Postmaster-General of the United States, do hereby fix the rates at which the telegraph communications aforesaid shall be sent, for the year commencing on the first day of July, A. D. eighteen hundred and seventy-three, as follows, namely:

The rate for all telegraphic communications known as the signal-service messages and reports shall be three cents for each word of said reports and messages for each circuit over which it may pass in accordance with the schedule of circuits and plans of the Chief Signal Officer of the Army, which are now adopted, or may hereafter be adopted by him for transmitting these dispatches, or such part thereof as he may designate, in such words or ciphers as may, from time to time, be directed by him. The amount thus estimated is to be taken in full payment for said dispatches; no additional allowance to be made for drops, office messages, or other services or special facilities required by the Chief Signal Officer for the correct and prompt transmission of said signal-service messages and reports.

The rate for all telegraphic communications, sent otherwise than over circuits established as aforesaid, shall be as follows, viz: One cent per word for each circuit through which it shall be transmitted, said rate to be computed subject to the following conditions, viz:

A distance of two hundred and fifty miles, as computed by the tables of the Post-Office Department, shall be deemed a circuit.

If, in computing circuits, there shall be found one or more circuits and a fraction of a circuit, such fraction shall be deemed a circuit.

If a communication shall be sent a distance less than two hundred and fifty miles, that distance shall be deemed a circuit.

All words of the communication transmitted are to be counted, excepting the date and place at which such communication is filed; all messages of less than twenty-five words, address and signature included, shall be rated as if containing twenty-five words, and all messages exceeding twenty-five words shall be rated by the exact number of words they contain, address and signature included.

JNO. A. J. CRESWELL,
Postmaster-General.

THE SERVICE.

SUCCESSORS TO

BLISS, TILLOTSON & CO.;

41 *THIRD AVENUE,*

CHICAGO, ILLINOIS,

MANUFACTURERS AND DEALERS IN

Telegraph Machinery and Supplies,

GALVANIZED AND PLAIN WIRE,

INSULATORS,

AND EVERY DESCRIPTION OF

OFFICE AND BATTERY MATERIAL

ALWAYS ON HAND.

INSTRUMENTS REPAIRED AT SHORT NOTICE.

CALLAUD BATTERY.

L. G. TILLOTSON & CO.,

SOLE MANUFACTURERS IN THE EAST.

ORDERS SOLICITED.

No. 8 DEY STREET

NEW YORK.

PENSACOLA TELEGRAPH CO.

C. L. LE BARON, *President.*

CHARLES LE BARON, JR., *Sec'y and Treasurer.*

PENSACOLA, FLORIDA.

OFFICES IN

PENSACOLA, FLA. FERRY PASS, FLA.

MOLINO, FLA. MILTON, FLA.

PENSACOLA JUNCTION, FLA. BAGDAD, FLA.

Connect with the lines of the WESTERN UNION TELEGRAPH COMPANY at Pollard, Ala.

Governed by the same Rules and Regulations as the Western Union Telegraph Company

WATTS & COMPANY,

Baltimore,

MANUFACTURERS OF

Electrical and Telegraph Instruments

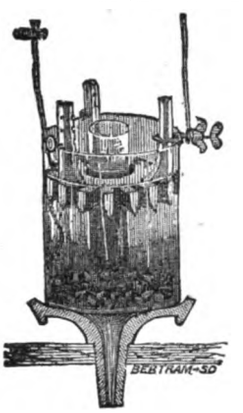
AND

MATERIAL OF EVERY DESCRIPTION,

RELAYS, KEYS, SOUNDERS, COMBINATION SETS, Etc., Etc.

Nickel Plated Goods a Specialty.

A VERY SUPERIOR MAIN LINE SOUNDER.



ENTIRELY NEW.

Furnished in a small black walnut box—which holds pens, pencils, paper, wire, pliers, etc., for opening temporary offices at breaks, etc. It is a complete railroad outfit, and supplies a want which has long existed.

SOLE MANUFACTURERS OF THE

NEW PATENT BALTIMORE BATTERY,

MADE IN THREE SIZES.

No. 1.
Size of Glass, 8x7½ inches,
Specially adapted to Railroad Signals, Printing Instruments etc., etc.

No. 2.
Size of Glass, 8 x 6 inches.
For Locals and Main.

No. 3.
Size of Glass, 7 x 5 inches.
For Light Main.

This Battery is most extensively used throughout the Country having proven the cheapest, and least trouble to maintain of any in the market.

Patented Dec. 31, 1872.

ALSO, SOLE MANUFACTURERS OF THE

Patent Circuit Closer Key,
O'Sullivan Self-closing Key,
Scott's Patent Hotel Annunciator

by which guests telegraph their wants to the clerk, and avoid waiting to have the boy come and see what is required.

ALSO, OF THE

PATENT BATTERY INSULATOR

shown, holding a cup of the Baltimore Battery in the above cut, which most effectually insulates the Battery as the drip passes off *through a hole in the Insulator.*

The Electrician of the Western Union Telegraph Company, Mr. PRESCOTT, says of it:—"I think your Battery Insulator a very admirably adapted for the purpose designed, and it ought to receive general adoption."

Also, ELECTRIC GONGS of all sizes.
RAILROAD SIGNALS.
SWITCH BOARDS, any Pattern.
A CHEAP DIAL INSTRUMENT for Private Lines.
All kinds of BATTERY MATERIAL.
WIRES.—Rubber, Kerite, Silk and Cotton Covered Office—all Sizes.

Insulators.

BROOKS, SCREW GLASS, RUBBER HOOK.
CROSS ARMS, PINS, BRACKETS.
Repairers' Tools constantly on hand.
Importers and Dealers in best English and American Galvanized Wire.
MANIFOLD PAPER, for Train Orders, etc. Also, AGATE PENS.

In fact, everything used in connection with TELEGRAPH LINES we are prepared to furnish, and equip any length of line in the shortest possible time. Having our own Foundry, we can furnish Brass Castings of any description at moderate prices.

Manufacturers and Dealers in

Telegraph Instruments and Supplies

OF EVERY DESCRIPTION,

38 Vesey Street, New York.

New and Superior patterns of

STANDARD TELEGRAPH INSTRUMENTS.

Their RELAYS, SOUNDERS, and KEYS which have been specially designed by Mr. F. L. Pope, are elegantly designed, thoroughly well finished and scientifically adapted to the service required and are recommended as SUPERIOR TO ANY HITHERTO OFFERED.

In addition to these ALL DESCRIPTIONS OF TELEGRAPH MATERIALS AND SUPPLIES are furnished, such as

INSULATORS, BATTERIES,
INSULATED WIRES,
CHEMICALS., ETC, ETC.

MAGNETIC AND DIAL INSTRUMENTS.

We have for sale also THE NONPAREIL TELEGRAPH INSTRUMENT for amateurs, learners and short lines.

A COMBINATION SET, comprising Sounder and Key on a handsome rosewood base.

Bradley's Box Relays and Sounders.

Bradley's Apparatus for Electrical Measurement.

Bradley's Naked Wire Helices and Magnet Spools to order, any desired size and resistance, at manufacturers' lowest price.

Descriptive Circular and Price Lists forwarded upon application to

F. L. POPE & CO.,

P. O. Box 6010 *38 Vesey St., N. Y.*

THE LECLANCHE BATTERY CO.

Offer for Sale this celebrated Battery,

SECURED BY LETTERS PATENT,

Of which they are the exclusive owners in this country.

Over 300,000 are now in use in Europe,

and have recently been adopted by the French Government in preference to the Calland, which had been used by them for several years.

WE RECOMMEND THEM FOR

Telegraphy (open circuit), Railroad Signals, Hotel Annunciators, Burglar Alarms, Electric Bells, Clocks, &c.

AMONG ITS NUMEROUS ADVANTAGES ARE—

ABSENCE OF ACIDS AND SALTS OF COPPER,

ITS GREAT CLEANLINESS,

WONDERFUL DURABILITY,

ECONOMY IN RUNNING EXPENSES,

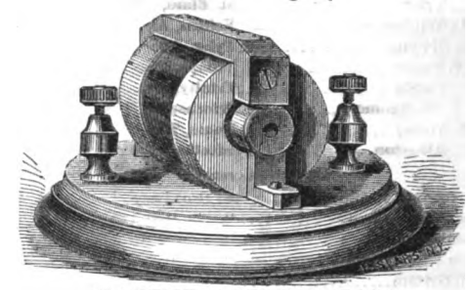
ENTIRE ABSENCE OF ODOR.

This Battery will last without any attention from six months to three years.

A large number of Cups are already in use in this country on Burglar Alarms, Electric Bells, &c., and are giving entire satisfaction. The Western Union has a number of Cups put up November 26th, 1872, that are still running.

For further particulars apply to

THE LECLANCHE BATTERY CO.,



No. 40 West Eighteenth Street.

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 18. NEW YORK, AUGUST 15, 1873. WHOLE NO. 139.

SIEMEN'S POLARIZED RELAY.

This instrument is in general use in England, and in many countries on the continent of Europe, and is regarded as an improvment on the ordinary Morse relay, particularly as it does not require any adjustable spring as a retractile force.

Figure 1 represents an upper view of this instrument, and Figure 2 the same in diameter through the center.

The relay consists of a steel magnet, *N S*, bent in a right angle, Figure 3, on whose leg *N* the soft iron cores *n n'* and the wire coils or belices *m m'* of an electro magnet are fixed, whilst at the extreme end of the other leg *S* is a small iron bar *c c'*, which operates as a relay lever and armature,—turning horizontally on its pivot *B*. The motion of this armature is limited by the metallic screw *D*, on the one side, and by the agate cap, *D'*, on the other.

Figure 3 represents the steel magnet *N S* more in detail.

On the leg of this magnet the iron coils *n n'* are attached, upon which the coils *m m'* are wound. The south pole *S* polarizes the tongue *c c'*.

Figure 4 represents the electro-magnet *m m'*, the steel magnet *N S S*, and the polarized tongue *c c'*, in perspective.

As soft iron, when placed on the pole of a magnet, becomes itself magnetised, and takes the same polarity with that with which it is connected, it follows that when *N* and *S*, Figure 2, represent the North and South poles of the steel magnet, then the upper ends, *n n'*, of the iron coil standing on the North pole, *N*, likewise form permanent North poles, and for the same reason the extreme end, *c'*, of the armature, *c c'*, which at *S* stands on a South pole, permanently a South pole. Therefore, the armature will be attracted equally by north poles *n* and *n'*, but if it be brought nearer to one than the other it will be held there because it is under the influence of a more powerful force. If the attraction between *n* and *C'* is predominate the armature lever will lay over on the point *D*, and if the attraction is greater between *n'* and *C'* it will incline on the agate point *D'*. It is evident that the latter position, where the local battery, which is put in between *A* and *B*, is open, corresponds with the position of rest of the ordinary relay.

When the key is closed at the remote station, and a line current is sent through the coils, *m m'*, one of the poles, *n n'*, becomes oppositely polarized.

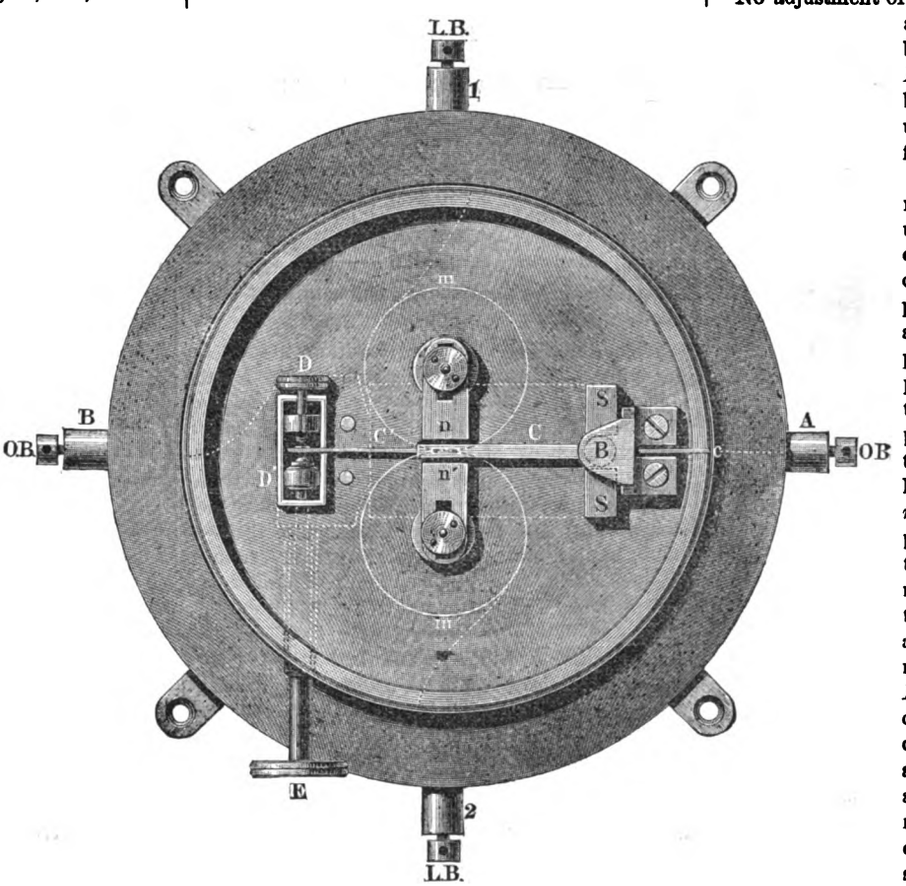

Figure 1.

Suppose that this current causes at *n* a north pole, and at *n'* a south pole, then the north magnetism already at *n* is increased, but destroyed at *n'*.

As the South magnetism at *c*, is however unchanged, the attraction of *n* toward *c'* is predominant, and the tongue of the lever *c c'* strikes against the contact screw, *D*, and closes the local circuit.

When the line current ceases the lever still remains in connection with screw, *D*, as then the electro-magnetism from *m m'* of course disappears, but the attraction between *C* and *n* is predominant on account of its being nearer.

The removal of the armature, *C C'*, to its former position can only be effected by a reverse current, which is produced at the remote station by a pole-changing key, the south magnetism being produced at *m*, and north magnetism at *m'*, by which the north magnetism already to be found at *n* is decreased and strengthened at *n'*, consequently the former attraction between *n* and *C'* is destroyed, and on the contrary the attraction between *n'* and *C'* predominates. The tongue *C C'* thus again strikes against the isolating point *D'* and interrupts the local circuit, whose poles are connected with *A* and *B*, and by it further with *C C'* and *D*.

No adjustment of the armature lever is required, after it has been properly placed by means of the regulating screw *E*, no matter which pole of the battery be to line, and thus the use of a spring as a retractile force is entirely dispensed with.

It is obvious that the polarized relay can be very advantageously used likewise for ordinary battery currents. For this purpose it is only required that the movable pole shoes *n n'* shall be placed at different distances from the polarized tongues *C C'*. The piece *n'*, which corresponds to the rest or *D'* side, must be placed nearer to the tongue *C C'* than piece *n*. In this case as long as no current passes through *m m'* the attraction of the north pole *n'*, by the south polarized tongue *C'*, increases that of the north pole *n*, and consequently the armature *C'* is constantly attracted by *n'*, and the tongue *C'* remains against the isolated point *D'* and interrupts the local circuit. When, however, a line current arrives of such a polarity as to form at *m* a north pole, and at *m'* a south pole, then the north magnetism already present at *n* is increased, and the south magnetism present at *n'* destroyed or replaced by south magnetism, so that the attraction of *n* and *C'* predominates, and accordingly the tongue *C C'* is drawn over to the opposite side and closes the local battery at *D*. It is true that with the breaking of the line current the magnetism at *m* and *m'* again ceases, but the north magnetism at *n* and *n'* caused by the steel magnet *M S* remains, and consequently the tongue at *n* should remain in the same position; but as the space for motion between *D* and *D'* is very small, only a little change is made in the distance of the tongue from *n* and *n'* on account of its movement towards *n*, and it has thus, just as before, on account of its position, a little more attraction for *n'* than

Digitized by Google

for n. As, therefore, C' stands nearer to n' than to n, the attraction of n' predominates and attracts the tongue C' back again, thus again interrupting the local battery until a new line current closes it.

The polarized relay is exceedingly sensitive on account of the absence of the retracting spring, which the electro magnet has not got to overcome, and also because the action of the poles n and n' on the armature C C' is a double one, attracting and repelling at the same time. As no regulating of the adjustment is required to meet the varying strengths of the line current, this relay is greatly preferred to the ordinary form, and it is very generally employed all over Europe.

To adjust the polarized relay place the pole shoes n and n' at a convenient distance apart, and then turn the screw B until the tongue b is brought as nearly as possible in the centre between the poles, so as to have equal room for adjustment on each side. The set screw D is then adjusted so that the motion of the tongue or armature lever shall be about $\frac{1}{10}$ of an inch between the insulated stud D' and the contact point. Adjusting screw E is then turned so that the armature, when no current is flowing, shall be slightly attracted by the pole bringing the tongue into contact with the agate point D'. If, after the instrument is

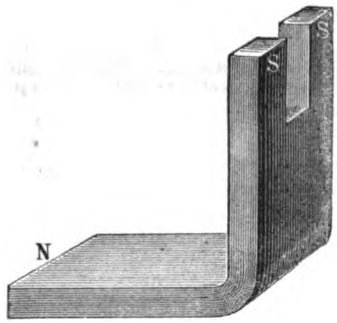

Figure 3.

so adjusted, the armature lever remains permanently in contact with the circuit closing point D when the distant station is sending, turn screw E to the right, so as to lessen the attraction of n and

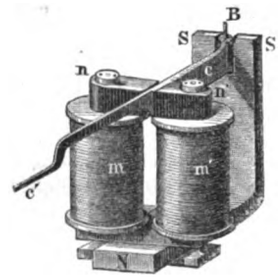

Figure 4.

increase that of n'. If this produces no effect, either place n a little farther from, or n' a little more to, the tongue or armature lever C' C until the desired result is obtained.

Sometimes this relay is combined with a galvanoscope, the same currents working both. On the top of the glass cover of the relay, under a small glass dome, is a single needle supported upon a point. When a current passes through the coils of the relay the polarization of the electro-magnet cores is altered, and the needle deflected. The operator who is receiving can therefore see when currents are arriving through the relay without employing a separate galvanoscope, as has hitherto been done.

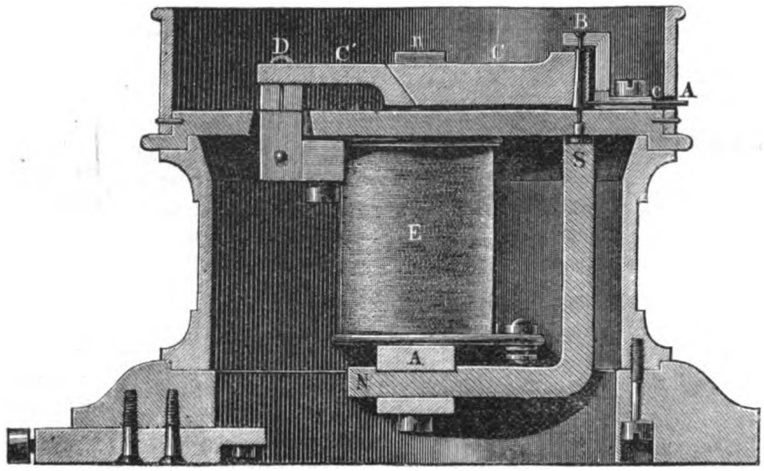

Figure 2.

SCIENCE—THE WORKER, THE APPLIER.

BY PROFESSOR JOHN TYNDALL, LL.D., F. R. S.

Dr. Tyndall concluded his course of lectures on Light at the Royal Institution, on Thursday, June 5, as he did also his lectures at New York, by a peroration, enforcing the paramount importance to material progress in the arts and manufactures of scientific research.

Science must be cultivated for its own sake, for the pure love of the truth, rather than for the applause or profit it brings. What was the motive that spurred on the men who have bequeathed to us the vast body of knowledge of which I have sought to give you some faint idea in these lectures? What the prize of their high calling for which they struggled so assiduously? What urged them to those battles and those victories over reticent Nature which have become the heritage of the human race? It is never to be forgotten that not one of those great investigators, from Aristotle down to Stokes and Kirchoff, had any practical end in view, according to the ordinary definition of the word "practical." They did not propose to themselves money as an end, and knowledge as a means of obtaining it. For the most part, they nobly reversed this process, made knowledge their end, and such money as they possessed the means of obtaining it. We may see to-day the issues of their work in a thousand practical forms, and this may be thought sufficient to justify it, if not ennoble their efforts. But they did not work for such issues; their reward was of a totally different kind. In what way different? We love clothes, we love food, we love fine equipages, we love money, and any man who can point to these as the result of his efforts in life justifies these efforts before all the world. He is a practical man. But I would confidently appeal to this assembly whether such things exhaust the demands of human nature? Given clothes, given food, given carriages, given money—is there no pleasure beyond what these can cover which the possessor of them would still covet? Your very presence here is an answer to my question. I need not tell such an assembly that there are joys of the intellect as well as joys of the body, or that these pleasures of the spirit constituted the reward of our great investigators. Led on by the whisperings of natural truth, through pain and self-denial, they often pursued their work. With the ruling passion strong in death, some of them, when no longer able to hold a pen, dictated to their friends the result of their labors, and then rested from them for ever.*

Could we have seen these men at work, without any knowledge of the consequences of their work, what should we have thought of them? To many of their contemporaries it would have appeared simply ridiculous to see men whose names are now stars in the firmanent of science straining their attention to observe an effect of experiment almost too minute for detection. To the uninitiated they might well appear as big children playing with not very amusing toys. It is so to this hour. Could you watch the true investigator in his laboratory, unless animated by his spirit, you could hardly understand what keeps him there.

Many of the objects which rivet his attention might appear to you utterly trivial; and, if you were to step forward and ask him what is the use of his work, the chances are that you would confound him. He might not be able to express the use of it in intelligible terms. He might not be able to assure you that it will put a shilling into the pocket of any human being living or to come. That scientific discovery may put not only pounds into the pockets of individuals, but millions into the exchequers of nations, the history of science amply proves; but the hope of its doing so is not the motive power of the investigator. It never can be his motive power. I know that I run some risk in speaking thus before practical men.

What, I would ask, are useful applications? Is man's body alone to be the object and arbiter of what is useful? Is there no nakedness of the mind to be clothed as well as nakedness of the body?—no hunger and thirst of the intellect to satisfy? Surely no two terms were ever so much distorted and misapplied with reference to man in his higher relations than these terms useful and practical. Let us expand the definitions of these terms until they embrace all the needs of man, his highest intellectual needs inclusive. It is specially on this ground of its administering to the higher needs of the intellect; it is mainly because I believe it to be wholesome as a source of knowledge, and as a means of discipline, that I urge the claims of science upon your attention.

But, with reference to material needs and joys, surely pure science has always a word to say. People sometimes speak as if steam had not been studied before James Watt, or electricity before Wheatstone or Morse, whereas, in point of fact, Watt and Wheatstone and Morse, with all their practicality, were the mere outcome of antecedent forces, which acted without reference to practical ends.

At the present time there is a cry for technical education, and it is the expression of a true national want; but there is no outcry for original investigation. Still without this, as surely as the stream dwindles when the spring dries, so surely will their

* Stephen Gray, on his death bed, described to a Committee of the Royal Society his electrical researches.

Digitized by Google

technical education lose all force of growth, all power of reproduction.

To keep society, as regards science, in healthy play, three classes of workers are necessary. Firstly, the investigator of natural truth, whose vocation it is to pursue that truth, and extend the field of discovery for the truth's own sake, and without any reference to practical ends. Secondly, the teacher of natural truth, whose vocation it is to give public diffusion to the knowledge already won by the discoverer. Thirdly, the applier of natural truth, whose vocation it is to make scientific knowledge available for the needs, comforts and luxuries of life. These three classes ought to coexist, and interact upon each other.

Now, the popular notion of science often relates not to science strictly so-called, but to the applications of science. Such applications are so astounding—they spread themselves so largely and umbrageously before the public eye—as to shut out from view those workers who are engaged in the profounder business of discovery.

Take the electric telegraph as an example, which has been repeatedly forced upon my attention of late. I am not here to attenuate in the slightest degree the services of those who, in England and America, have given the telegragh a power so wonderfully fitted up for public use. Assuredly they earned a great reward, and assuredly they have received it. But I should be untrue to you and to myself if I failed to tell you that, however high in particular respects their claims and quality may be, practical men did not discover the electric telegraph. The discovery of the electric telegraph implies the discovery of electricity itself, and the development of its laws and phenomena. Such discoveries are not made by practical men, and they never will be made by them, because their minds are beset with ideas which, though of the highest value from one point of view, are not those which stimulate the original discoverer. The ancients discovered the electricity of amber, and Gilbert, in the year 1600, extended the force to other bodies.

Then followed other inquirers. But this form of electricity, though tried, did not come into use for telegraph purposes.

There appeared the great Italian, Volta, who discovered the source of electricity which bears his name, and applied the most profound insight and the most delicate experimental skill to its development. Then arose the man who added to the powers of his intellect all the graces of the human heart, Michael Faraday, the discoverer of the great domain of magnets, electricity. Œrsted discovered the deflection of the magnetic needle, and Arago and Sturgeon the magnetization of iron by the electric current. The voltaic circuit finally found its theoretic Newton in Ohm, while at Princeton, Henry pushed forward the course of experimental inquiry.

Here you have all the materials employed at this hour in all the forms of the electric telegraph. Nay, more: Gauss, the celebrated astronomer, and Weber, the celebrated natural philosopher, both professors in the University of Gottingen, wishing to establish a rapid mode of communication between the observatory and the physical cabinet of the university, did this by means of an electric telegraph. The force, in short, had been discovered, its laws investigated and made sure, the most complete mastery of its phenomena had been attained, nay, its applicability to telegraphic purposes demonstrated by men whose sole reward for their labors was the noble joy of discovery, and before your practical men appeared at all upon the scene.

Are we to ignore all this? We do so at our peril. For I say again, that, behind all your practical applications, there is a region of intellectual action to which practical men have rarely contributed, but from which they draw all their supplies. Cut them off from this region, and they become eventually helpless. In no case is the adage truer, "Other men labored, but ye are entered into their labors," than in the case of the discoverer and the applier of natural truth.

CORRESPONDENCE.

STUPIDITY, OR WHAT?

To the Editor of the Journal of the Telegraph:

Late on the night of June 29th, we received at this office a message from San Luis Potosi, Mexico, addressed Rodolpho Pigeon or Pirgeon, 93 Old Levee street. Knowing that there is no such street in New York, and the gentleman's name not appearing in our City Directory, I gave the message to one of my best messengers, and directed him to inquire at the Mexican Consul's, to see if he knew of any such person. The party was not known at the Consul's, and the message was returned to me undelivered.

Knowing that there is such a street as Old Levee street in New Orleans, I asked that office, at 9.45 A. M., June 30th—as stated in the previously printed communication—and received his reply at 1.35 P M., same day.

My reasons for pursuing this course were: 1st, because I was almost certain that the message was "bulled," and intended for New Orleans, not New York; 2d, because the Mexican lines are nearly always out of order, and it frequently takes three or four days, and sometimes a week, to get any reply from offices on that line. For this reason, I did *not* notify the sending station that the message was undelivered, and ask that station for better address, as is usual in such cases.

In conclusion, I beg to say that, by my course in this case, I avoided the necessity of sending one office message to San Luis Potosi (nearly double the distance to New Orleans) and one reply from that office. I also avoided a delay in delivery of from one day to one week. As this communication evidently comes from New Orleans, I think that office should investigate, how it was possible that a message from Mexico, sent to New Orleans for delivery at 93 Old Levee street, is allowed to pass through that office and come to New York, compelling me to return the message to that office by telegraph, and in this particular case acting as delivery clerk for New Orleans office.

I now submit the above to a fair and candid consideration, and ask, was this *stupidity, or what?*

J. D.

To the Editor of the Journal of the Telegraph:

In an article in the JOURNAL of July 1st the suggestion is made, that each office be supplied with mourning blanks and envelopes, to be used only for death messages. Perhaps, if "K." would try this plan, it would answer just as well.

I always write the word "*Death*" in large, plain letters on the envelope containing such a message; it takes but a moment to do it, and, I think, answers the same purpose as a mourning envelope.

It is quite interesting to read the different opinions of operators in regard to a change in the telegraphic alphabet.

I am not going to say which is best for the Company to adopt, because I don't know, but, in only a few years' experience, I do not see how a careful operator can make mistakes with the Morse alphabet.

M.

PHILADELPHIA, Aug. 7th, 1873.

To the Editor of the Journal of the Telegraph:

With your permission I will give my view upon the "Proposed Change of Alphabet." The prevailing opinion among operators, judging from the JOURNAL's correspondence column, seems to be, that errors occurring in transmitting messages arise from the use of spaced letters in our alphabet. Now, in my limited experience, I find such is not altogether the case, although, at the first glance, those much abused spaced letters seem to be the sole cause. Upon investigation, I find *the trouble proceeds from certain letters being formed from a combination of the dot letter E with the space letters.* To illustrate, - - - - S. E. combined, form Z., as also - . - E. S. form, and the cause of the Gill and Pie error. Now, do away with the dot letter, and errors of that kind cease, and then terms will not be misconstrued into toims, as was the case a few weeks since. Substitute - - — — for - E, and our alphabet is perfect, as far as space letters are concerned. I know such a change would be received with much opposition, on account of the frequent occurrence of the letter E, and the extra amount of time it would take to transmit it. But as "A.," of San Francisco, says: "If a message can be received in sixty seconds with one alphabet, and there is any greater ease and certainty in another alphabet, which requires sixty-one seconds, the latter might be preferable, *speed* wthin certain limits, being subordinate to ease and security." This I believe to be the correct view to take. Suppose we can work faster with our Morse alphabet than any other, does the income accruing from the extra amount of business transmitted by it equalize those costly errors the Western Union Company have to pay for? I think not. There is one other letter that gives considerable trouble to operators generally—the single dash letter T or L. If they were always properly made, no trouble could arise, but they are not, and it is doubtful if they ever will be. Experts judge from the context what letter is intended, and young operators, who "won't break," occasionally get it down wrong.

We could use - ——— for L, retaining the single dash for T, thus perfecting our alphabet, by making only two slight changes instead of a dozen or more, as would be the case if we adopt the Continental Code.

W. T. B.

To the Editor of the Journal of the Telegraph:

Suppose a party came in the office with a message to J. Camp & Co., Philadelphia, Pa., no number or street on message, and party neither knows number nor street, are we bound to receive the message and forward it? A case here in this city is in dispute. The rules of the Company are not explicit on this point.

B. S.

You are bound to receive the message and send it forward. The number and street would probably be found in the Directory.

NORTHVILLE, Mich., June 9, 1873.

To the Editor of the Journal of the Telegraph:

I do not think the Morse alphabet needs changing. Operators should be more careful in sending the spaced and initial letters. I like the suggestion of your correspondent, in regard to a stop after initial letters, but would suggest the use of our comma . — . —as being shorter and more likely to be understood than the continental .. .. .. How many of the 5,000 R. R. offices are under the immediate control of R. R. Superintendents? I would like to hear from these superintendents. My opinion is that very few of them would consent to change, and unless they do change, we, who work on railroad lines, would have to do railroad business by Morse, and work with Western Union repeating offices by some other alphabet.

A.

The acknowledgment of receipt of any assessment is to be understood as an acknowledgment for all previous assessments:

ACKNOWLEDGMENT OF RECEIPTS FOR ASSESSMENTS 44, 45 AND 46 UP TO AUGUST 13TH.

13, 22, 26, 33, 37, 54, 61, 67, 70, 72, 74, 75, 80, 82, 88, 89, 90, 93, 95, 97 98, 101, 107, 108, 120, 134, 136, 139, 141, 142, 144, 146, 166, 169, 179, 181, 183, 188, 189, 190, 191, 193, 197, 198, 200, 218, 220, 231, 240, 244, 247, 254, 255, 256, 257, 267, 277, 289, 303, 311, 323, 328, 330, 350, 353, 354, 367, 371, 372, 376, 378, 379, 385, 388, 391, 406, 416, 430, 431, 434, 438, 456, 463, 466, 468, 469, 470, 471, 474, 475, 481, 482, 514, 516, 526, 527, 548, 552, 554, 560, 565, 569, 574, 576, 577, 579, 587, 594, 603,604, 622, 628, 636, 646, 649, 655, 656, 662, 663, 664, 665, 669, 670, 672, 684, 685, 690, 694, 702, 708, 711, 714, 715, 725, 735, 737, 738, 741, 750, 751, 756, 772, 778, 803, 812, 820, 825, 831, 842, 848, 855, 858, 859, 869, 870, 873, 883, 899, 908, 911, 915, 922. 938, 939, 942, 952, 976, 995, 998, 1005, 1008, 1011, 1013, 1023, 1024, 1039, 1044, 1055, 1056, 1058, 1073, 1074, 1075, 1076, 1081, 1085, 1099, 1102, 1144, 1147, 1148, 1152, 1155, 1156, 1157, 1159, 1160, 1162, 1164, 1178, 1185, 1193, 1194, 1204, 1222, 1225, 1226, 1227, 1231, 1237, 1238, 1239, 1240, 1241, 1259, 1262, 1263, 1267, 1270, 1273, 1282, 1287, 1288, 1292, 1294, 1307, 1308, 1309, 1311, 1312, 1313, 1314, 1315, 1317, 1318, 1319, 1320, 1321, 1322, 1325, 1345, 1353, 1354, 1355, 1358, 1360, 1363, 1364, 1365, 1372, 1376, 1383, 1399, 1407, 1412, 1417, 1418, 1419, 1425, 1426, 1437, 1438, 1440, 1449, 1451, 1452, 1453, 1454, 1455, 1456, 1459, 1461, 1462, 1484, 1487, 1500, 1501, 1506, 1507, 1508, 1511, 1515, 1516, 1517, 1519, 1522, 1524, 1532, 1537, 1539, 1542, 1543, 1552, 1555, 1558, 1559, 1565, 1580, 1582, 1585, 1590, 1593, 1594, 1610, 1611, 1612, 1614, 1615, 1623, 1625, 1626, 1629, 1644, 1652, 1656, 1660, 1661, 1662, 1663, 1665, 1680, 1681, 1682, 1684, 1685, 1687, 1688, 1699, 1709, 1710, 1711, 1713, 1719, 1720, 1731, 1732, 1734, 1738, 1738, 1738, 1745, 1763, 1773, 1774, 1775, 1791, 1794, 1795, 1796, 1797, 1798, 1799, 1800, 1804, 1811, 1812, 1813, 1814, 1815, 1817, 1823, 1824, 1831, 1839, 1840, 1841, 1842, 1844, 1845, 1847, 1848, 1852, 1867, 1768, 1869, 1872, 1882, 1883, 1884, 1900, 1901, 1908, 1911, 1912, 1913, 1914, 1915, 1916, 1920, 1921, 1923, 1924, 1925, 1926, 1927, 1957, 1965, 1966, 1969, 1984, 1987, 1994, 2002, 2014, 2015, 2023, 2024, 2036, 2038, 2045, 2048, 2058, 2059, 2060, 2072.

FOR 43 AND 43.

294, 847, 766, 1134, 1135, 1136, 1234, 1722, 1778, 1779, 1780, 1916, 1930, 1952, 1973.

FOR 44.—1040.

FOR 45.—1251, 2041.

The following statement shows the amounts paid in under the assessments of June 7th:

No. 42. for the benefit of the heirs of J. R. Dunlap.....$1,255 00

No. 43, for the benefit of the heirs of F. S. Belden.....1,275 00

We are notified of the death of Robt. S. Fowler, which occurred at Dubuque, Ia., on July 21st; also that of Wm. P. Trites, at Monroe, La., July 29th.

DIED.

WELTER.—At Summit, N. J., August 6th, Eddie George, only child of T. S. and Carrie C. Welter, aged 5 months and 23 days.

Dearest Eddie, thou hast left us,
And thy loss we deeply feel:
But the hand that has bereft us
Will in time our sorrow heal.

ELECTRIC BALANCE AND AN ELECTRO-STATIC PHENOMENON.—*M. Volpicelli.*—The law of electro-static action revealed by Coulomb's balance depends on a considerable number of causes or forces, as follows: 1. Repulsion or attraction between the electric charges. 2. Curvilinear induction between the two spheres. 3. Rectilinear induction between them. 4. The attraction of the substances surrounding the spheres. 5. Electrization of the insulating rods. 6. Non-uniformity in the distribution of electricity on the spheres. 7. Want of reciprocal rectilinear action of the parts of the charge distributed on the surfaces not facing each other. 8. Increase of the initial charges through induction of one sphere on the other. 9. The circumstance that one may not refer entirely to the centre of one of the two spheres the electric charge which acts on the other. 10. The loss during experiment, of part of the induced electricity of the first kind, and the diminution thus produced. 11. The imperfect elasticity of the suspension thread, its variability with temperature, and its hygrometric state (if not metallic). Thus it appears that the two investigations of the law, one mathematical, the other experimental, are hardly comparable. M. Volpicelli adds some remarks on an experiment described thus in *Les Mondes:* "Let the knob of a gold-leaf electroscope be touched with a bar of vulcanized caoutchouc electrified negatively by rubbing with cat-fur; then remove the rod. Next bring near to the knob a body electrified negatively; the divergence of the leaves diminishes. This phenomenon would be inexplicable if the electroscope were charged negatively. Experiment shows, then, that after removal of the rod there remains an excess of positive fluid." He asks, whence this positive excess, and traces it to the fact that electrified non-conductors, unless moistened, do not communicate their electricity to metals they touch, but act merely by induction.

THE RATES OF POSTAGE.

[*From and after July* 1, 1873.]

Postal cards, one cent each, go without further charge to all parts of the country.

Postal cards can be sent to Canada, New Brunswick, Nova Scotia, or Prince Edward's Island, by putting on a one-cent stamp.

All letters, to all parts of the United States, 3 cents per half-ounce.

Local or "drop" letters—that is, for the city or town where deposited—2 cents if delivered by carriers, and 1 cent if there is no carrier system.

For newspapers and magazines, regularly issued and sent to regular subscribers, the following rates per quarter of three months, payable in advance at the office where received:

Dailies	35 cents.
Six times a week	30 cents.
Tri-weeklies	15 cents.
Semi-weeklies	10 cents.
Weeklies	5 cents.
Semi-monthlies, not over 4 ozs	6 cents.
Monthlies, not over 4 ozs	3 cents.
Quarterlies, not over 4 ozs	1 cent.

Books, 2 cents for each 2 ounces, or fraction thereof.

All other printed or miscellaneous matter, as pamphlets, transient newspapers, handbills, circulars, proof-sheets, photographs, book manuscripts, etc., and also seeds, cuttings, bulbs and roots, 1 cent for each two ounces, or fraction thereof, always to be pre-paid. Copies of the JOURNAL come within this limit of two ounces, and the postage upon irregular numbers is 1 cent each.

Manuscript for publication in newspapers, magazines, etc., is subject to letter postage.

Undelivered letters can be re-sent to a new address without additional charge.

Stamps cut from stamped envelopes are rejected by the post office.

Letters to all parts of the New Dominion (Canada), 10 cents per half ounce, if unpaid; paid, 6 cents; newspapers, 2 cents each.

The following are the postal rates with Europe, pre-payment in the case of letters being optional, that of newspapers compulsory. Unless otherwise indicated, the rates for letters are for the half ounce, or fraction thereof, and those for newspapers for four ounces, or fraction thereof:

To Great Britain and Ireland, letters, 6 cents; newspapers, 2 cents. France, letters, direct mail, 10 cents; *via* England, for one-third ounce and under, 10 cents; from one-third to one-half ounce, 16 cents; newspapers, 2 cents each. Spain, letters, under one-third ounce, 16 cents; one-half ounce and under, 28 cents; newspapers, 2 cents each. All parts of Germany, including Austria, letters, direct mail, 6 cents; closed mail, *via* England, 7 cents; newspapers, 4 cents. Denmark, letters, direct mail, 9 cents; newspapers, 2 cents each. Switzerland, letters, direct mail, 10 cents; *via* Bremen or Hamburg, 8 cents; newspapers, 4 cents. Italy, letters, direct mail, 10 cents; newspapers, 4 cents. Russia, letters, direct mail, 11 cents; closed mail, *via* England, 12 cents; newspapers, 6 cents. Norway, letters, direct mail, 11 cents; closed mail, *via* England, 12 cents; newspapers, 8 cents. Sweden, letters, direct mail, 10 cents; closed mail, *via* England, 11 cents; newspapers, 8 cents. Turkey, European and Asiatic, letters, direct mail, 11 cents; closed mail, *via* England, 12 cents; newspapers, 7 cents. Egypt, letters, direct mail, 16 cents; closed mail, *via* England, 17 cents; newspapers, 9 cents.

For Asiatic countries, the half-ounce limit for letters, and the four ounces for newspapers, still holding good:

To Australia, letters, *via* Southampton, 16 cents; *via* Brindisi, 22 cents, to be pre-paid; newspapers, 4 and 8 cents by the respective routes. British India, letters, *via* San Francisco, 10 cents; *via* Southampton, 22 cents; *via* Brindisi, 28 cents, to be pre-paid; newspapers, *via* San Francisco, 2 cents each; by the other routes, 6 and 8 cents, respectively, per four ounces or fraction. China, letters, *via* San Francisco, 10 cents; *via* Brindisi, 23 cents, to be pre-paid; newspapers, 2 cents each. Japan, letters, *via* San Francisco, 10 cents; *via* Brindisi, 34 cents, to be pre-paid; newspapers, 2 cents each by the former route, and 8 cents per 4 ounces by the latter.

AUGUMENTATION OF THE INDUCTION SPARK.

Everybody is acquainted with the experiment which consists in placing in communication the two coatings of a Leyden jar with the two ends of the secondary wire of an induction coil. The length of the spark is reduced considerably, but the brilliancy and noise are, on the contrary, increased.

I wished to see the effect of large insulated metallic surfaces, placed in contact with the two ends of the secondary wire, the two surfaces being separated from each other, so as not to produce the effect of a condenser.

For metallic surfaces I took frames having each about eleven square feet covered with silk, doubled with paper, upon which had been fixed plates of tin. The spark burst between two insulated points, which can be made to approach or recede from each other at will.

So long as one or more plates of tin communicate with one of the poles only, the spark is in no way modified; but so soon as the other pole of the secondary wire is in contact with the plates of tin of the same surface as the first, the brilliancy of the spark increases and its length diminishes. The increase of the surface produces an increase in the brilliancy and the noise of the spark, and a new diminution in its length. If one of the metallic surfaces be greater than the other, the effect does not surpass that which two surfaces equal to the smallest produce.

The effect of the plate becomes more sensible by the drawing near of the points of the excitor, and the spark breaks out into a great number of tracks of fire; but if the distance of the points is reduced to about one and a half inches, the effect of the surface seems to disappear.

When in place of the large metallic plates, metallic wires or ribbons of tinsel are employed, three-fourths to one inch in width, well insulated by means of glass supports or silk cords, we then obtain, by the use of equal surfaces, much more intense effects.

Fifty-four yards of these metallic ribbons, placed in contact with each end of the secondary wire, making a total of 108 yards, greatly increase the brilliancy and the noise of the spark.

The stronger the induction, the more marked the effect; this is what I have proved lately, by means of a powerful apparatus, which M. Ruhmkorff has been good enough to place at my disposal. It is necessary to be careful, in order to obtain the greatest possible effect, to make the two ends of the metallic ribbon communicate with each point. If the ribbon be too long, it becomes necessary to establish a greater number of similar communications.

In general the effects are the much more intense when the insulated metallic surfaces are greater, more divided, and the different parts are more separated from each other.—*C. M. Guillemin, in Journal de Physique.*

FOREIGN TELEGRAPHIC ITEMS

THE WEST INDIA AND PANAMA TELEGRAPH CO.

A circular was issued on the 3d of May to the shareholders of the West India and Panama Telegraph Company, inviting subscriptions at par, in shares of £10 each, for the £250,000 Preference Share Capital bearing 10 per cent., recently authorized, to restore and complete the Company's property. The circular calls special attention to the facts that the ordinary share capital issued and fully paid up is £571,910; that the only debenture capital authorized is £50,000; that the Company's system extend altogether to about 1,800 miles, and possess subsidies amounting to £18,500 annually; that the gross earnings on an incomplete system, besides these subventions, amounted last year to £27,000, and that large receipts may be anticipated when the connection between Jamaica and Colon is completed, which will be by the end of the present year. The new issue, besides its preference, will be entitled to participate in all profits on the entire capital above 10 per cent., but may either be paid off at the end of five years at 10 per cent. premium, or the holders may convert into ordinary shares at £110 for every £100.

Since the circular was issued the new preference stock has been successfully placed in London, and there is now every prospect of the system of cables connecting the West India islands and Panama with those in the United States being completed, and the fact that Mr. Cyrus Field has joined the board is regarded with favor.

DIRECT UNITED STATES CABLE.

The statutory meeting of this company was held on Wednesday, July 9th, at the Cannon Street Hotel, London; Mr. E. H. Lushington in the chair.

The chairman said the meeting was formal, the object being to appoint an auditor. The Company was constituted in March last, and, unfortunately for them, at that time the great cry was coalition. It was determined by various companies that a large amalgamated company should convey messages from this country to the United States, and that everybody should be subject to their laws and regulation. He was happy to say, however, that this company succeeded in raising the necessary funds, and the directors had now completed the preliminary arrangements with Messrs. Siemens & Company, who were collecting materials for the purpose of constructing the cable, and who were prepared to do all to ensure its safe laying that modern science would allow them to do. They had determined to build a vessel for the purpose, and altogether the directors believed that, in placing the contract in the hands of these gentlemen, they had consulted the best interest of the shareholders. In conclusion, he stated that the directors were determined to act by themselves, and not to enter into any amalgamation whatever.—*The Railway News.*

THE report of the directors of the Eastern Telegraph Company recommends a dividend of 5*s.* per share, making, with the three previous payments, a total dividend for the year at the rate of 7 per cent., and states that they have carried to the reserve fund £42,958, thus raising it to £82,844.

THE telegraph line from Heligoland to Hamburg, constructed by the United German Telegraph Company of Berlin, was opened one day last week for use, by the despatch of a message from Lieutenant-Colonel Maxse, Governor of Heligoland, to the directors of the company.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
August 15, 1873.

To all Offices on W. U. Lines:

The following changes and additions have been made since the date of the last circular:

GENERAL INFORMATION.

Messages may be taken for Brandy Wine Springs and Stanton, Del. They will be delivered from Newport, Del. Charges for delivery, 50 cents.

Carr, Ill., changed to Bluff Hall, Ill.

Plank Road, Ill., closed.

Manteno, Ill., re-opened.

Syracuse, Ks., closed.

Messages may be taken for Swampscott, Mass., and Clifton House, in Swampscott, to be delivered from Lynn, Mass. Delivery charges, 75 cents for former, and $1.25 for latter.

Big Rapids, Mich., is now a W. U. office; square 250; check direct.

The office at Otsego, Mich., square 260, is in Allegan Co.

Luray, Mo., closed.

Table Rock, Neb., now in square 502, will hereafter be square 465.

Cape May, C. H., N. J., closed.

Business for Dun Ellen, N. J., will hereafter be checked direct.

Five Mile Point, Otsego Lake, N. Y., re-opened, square 57.

Little Mountain, O., re-opened.

Douglassville, Penn., closed.

White Horse, N. J. changed to Kirkwood.

Logan Iron Works, Pa., is in Mifflin Co. and not Juniata Co., as published in tariff book.

Ralston, Pa., is now a W. U. office, square 93. Check direct.

The office published in JOURNAL of April 15, 1873, as Clifton, Pa., should read Clinton, Lawrence Co., Pa.

* Wellspoint, "	65	4	470	"	

It is found that quite a number of offices use square rate for tariff to points to which the State Rates should apply. THE STATE RATES, AS PER INSTRUCTIONS, "SHOULD BE USED WITHOUT REFERENCE TO SQUARE RATES," WHETHER THE STATE RATES ARE LOWER OR HIGHER THAN THE SQUARE RATES.

Offices having "Special Sheet A," will check Donaldson, Pa., 25 cents more than "special rate" to Philadelphia. The square rate not to be increased.

CUBA CABLE BUSINESS.

The Cable between Jamaica and Porto Rico, has been repaired, and telegraphic communication is now complete as far as Trinidad.

The Cable between Trinidad and Demerara, in the West Indies, is broken, and messages for Demerara and Berbice, are now delivered from Trinidad by steamers on 6th and 21st of each month.

The following rates via. Cuba Cable, will apply hereafter, and should be used in connection with the "RULES" for Cuba Cable business, published in "Supplement No. 3," "Journal" of July 15th, 1873:

Tariff, in Gold.

NOTE.—In addition to the following rates to Havana, there is a Spanish Government tax of 40 cents for 10 words and 40 cents for each additional 10 or fraction of 10 words.	For Ten Words.	For each Additional Word.
To or from Havana, Cuba, and any office of the Western Union Telegraph Company, in the United States, east of the Mississippi River, including St. Louis, Mo.	$5 00	$0 40
To or from any office of the Western Union Telegraph Company, west of the Mississippi River, except St. Louis, Mo.	6 00	0 50
To or from Offices in New Brunswick and Nova Scotia.	6 00	0 50

Official Messages of the Spanish and United States Governments will be charged less than the above rates by $1.75 per each message of ten words or less, and eighteen (18) cents for each additional word. All such messages must be signed officially and the prefix "G" must precede the check.

On messages to the following named offices in Cuba, beyond Havana, collect, in addition to the foregoing rates, the Spanish local tariff, viz: Forty (40) cents, gold, for ten words or less, and forty (40) cents, gold, for each additional ten words or fraction of ten words.

The government tax does not apply on messages to these points:

Batabono,	Los Palacios,
Bajucal,	Los Punas,
Bemba,	La Mulata,
Bocu Du Sagua,	Matanzas,
Bayamo,	Mariel,
Bahia Honda,	Pinar Del Roi,
Consolacion Del Sur,	Paso Real,
Colon,	Puerte Principe,
Cardenas,	Remedios,
Cienfuegos,	San Antonio,
Caibarien,	Santo Domingo (Coloniado),
Cabanas,	Sagua,
Ciego De Avila,	Santo Spiritu,
Cuba,	San Diego De Nunez,
Guanaja,	Trinidad,
Guarinaro,	Union De Reyes,
Guines,	Villaclara,
Jignani.	

	From United States, East of Mississippi River, including St. Louis. GOLD.		*From United States, West of Miss. River, excluding St. Louis; and from New Brunswick and Nova Scotia.* GOLD.	
	1st ten words.	*Each Add'l word.*	*Ten words.*	*Each Add'l word.*
Santiago	$6 25	$ 53	$7 25	$ 63

Berbice	17 50	1 66	18 50	1 76

Messages to Panama, Valparaiso, and all points in South America can be mailed at Kingston, Jamaica, at above rates, with twenty-five cents in addition for postage.

ATLANTIC CABLE BUSINESS.

We are notified that the Hong Kong and Shanghai Cable is repaired; messages can now be sent by telegraph direct to Shanghai. The Shanghai and Nagasaki Cable is still interrupted.

CHANGE IN RATES

To and from Points in Canada.

On and after September 1st, 1873, the rate between Western Union offices in the United States and points on other lines in Quebec, Ontario and New Brunswick, will be 30, and 2 for other lines, and as given below for Western Union lines.

Unless otherwise stated, the amounts indicate the "tariff for this line," to Ontario, Quebec and New Brunswick:

Maine, New Hampshire and Vermont	$0.45 and 3
Massachusetts (except Boston), Rhode Island and Connecticut	.60 and 4
New York (except New York City) to	
Quebec and Ontario	.45 and 3
New Brunswick	.70 and 5
New Jersey, Ohio and Pennsylvania, to	
Quebec and Ontario	.60 and 4
New Brunswick	1.00 and 7
Delaware, Maryland, District of Columbia, Virginia, Illinois (except Chicago) and Wisconsin (except Milwaukee)	1.00 and 7
Indiana, Kentucky and West Virginia,	
To *Quebec and Ontario*	.85 and 5
New Brunswick	1.00 and 7
To Michigan	.50 and 3
Iowa, Missouri, Minnesota, North Carolina and Tennessee	1.20 and 8
South Carolina	1.45 and 10
Alabama, Arkansas, Florida, Georgia, Mississippi, Kansas and Nebraska	1.70 and 11
Louisiana and Indian Territory	2.00 and 13
British Columbia, California, Colorado, Idaho, New Mexico, Montana, Nevada, Oregon, Texas, Utah, Washington Territory and Wyoming	2.50 and 17

Boston, Mass., New York City, Chicago, Ill., and Milwaukee, Wis., will be specially instructed.

MESSAGES WILL BE SENT AND CHECKED AS HERETOFORE.

WM. ORTON, President.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, August 6th, 1873.

Executive Order No. 150.

No words in messages after the signature will be transmitted free for customers. The signature embraces simply the name. Titles of every description, addresses, the word "answer," or any other words after the signature, must be counted and charged for.

WM. ORTON, President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, August 7th, 1873.

TO TRANSFER AGENTS:

Hereafter, the titles, "Manager" and "Transfer Agent," or T. A., will not be added to transfer messages. Transfer agents and managers being well known, there is no necessity for using such titles, and no propriety in charging the customers for them.

On and after August 18th, Middletown, Pa., will be added to the list of money order offices in D. H. Bates' district, and Catawissa, Pa., in same district, will be closed as a money order office.

On and after August 18th, Washington, Pa., will be added to the list of money order offices in C. O. Rowe's district.

Cimarron, N. M., and Los Vegas, N. M., in W. B. Hibbard's district, have been closed as money order offices.

GEO. H. MUMFORD, Vice-President.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is over 8,000. It goes to every State, Territory and Province on the Continent. It has become a necessity, and is always welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, AUGUST 15, 1873.

In the JOURNAL of June 16th we announced that anything and everything, although not to be found as words in Webster's Dictionary, had been incorporated, by custom, into the language, and are each counted as one word. This statement should be considered as applicable to domestic messages only, as anything and everything are each counted as two words over the lines of the Cable Companies.

We recently called attention to what seemed to be an inexcusable use of the right to send office messages, based upon a communication from New Orleans. We now present, in another column, an explanation of the circumstances under which the message was sent, which materially changes the aspect of the case. Unexplained, the message was open to criticism, but, as explained, it shows a commendable exercise of discretion on the part of the sender, which it would be well for the service if all the Company's employés would pattern after.

PUTTING POSTAL CARDS IN SEALED ENVELOPES.

It is curious to note the great care and ingenuity which some people display in wrongly doing a very simple duty. Recently, we had an illustration of this kind, which was rather amusing. A well-meaning and painstaking person, who was evidently actuated by a laudable desire to utilize the new postal cards, wrote a communication upon one of them, and then cautiously placed it in an envelope, carefully attached a three cent postage stamp, and mailed it to St. Johns, N. B. Up to this point the whole transaction had been prudent, if not entirely in accordance with the more usual practice, but, in affixing that three cent postage stamp, the bounds of prudence were overstepped, and the penalty was exacted from the receiver of the letter in the shape of a ten cent. charge for insufficient prepayment of postage. Now, if the communication had been written upon ordinary paper, the postage, if prepaid, would have been six cents. If the postal card had not been placed in the sealed envelope, it would have required only an additional one cent stamp for the Canadian postage. Thus, a want of knowledge and of judgment entailed an unnecessary expense of twelve cents on the postage of a single postal card.

MISAPPROPRIATION OF SAVING BANK FUNDS FOR POSTAL TELEGRAPHS.

The matter of the misappropriation of the funds of the Post Office Savings Banks by the Telegraph Department, which has attracted so much attention in England during the past six months, was fully discussed in the House of Commons on the 30th ultimo, and resulted in the presentation of a resolution of censure, which was amended by the substitution of regret for the act, and adopted. The case is briefly this: In 1869 Parliament granted seven millions of pounds sterling for the purchase and extention of the Telegraphs, but when this sum was expended, Mr. Scudamore, the head of the Telegraph Department, and Secretary of the Post Office, did not stop his extensions until Parliament had made another appropriation, but used the funds belonging to the Savings Banks and Money Order business to the amount of over half a million pounds for carrying on the work. In 1871 another grant of one million pounds for the Telegraph was made by Parliament, but as three-fifths of this sum was for liabilities and over expenditure already incurred, the balance was soon expended, and Mr. Scudamore again repeated his former operation of appropriating other funds without authority,—the Post Office having uncontrolled power of dealing with balances to the extent of a million pounds in excess of its legitimate requirements. It appears that the unauthorized advances thus made for the operation of the telegraph since the last appropriation have amounted to £890,000, of which the greater part was expended within the financial years—1872-'73. This vast sum of money was mainly derived from three sources, viz:—Money Order business, Post Office Savings Banks, and Post Office receipts proper. There is no pretence that Mr. Scudamore made a bad use of the money. Everybody admits that he used it for the good of the service, and that if he had not assumed the responsibility of taking the funds and applying them as he did, the telegraphs would have failed of meeting the wants of the public. The difficulty, however, is that he took them without authority, and technically without the knowledge of his superiors, although they must have known, or ought to have known, that he was expending upon the telegraph annually much more money than he was receiving.

When the resolution of censure was pending in Parliament Mr. Gladstone said "the conduct of Mr. Scudamore may be a very proper subject for animadversion, but he is no fit subject for the censure of this House. Mr. Scudamore has committed a great error, but that error is followed by still greater services, and upon the merits of this case I refuse to censure him."

The truth is that the Government knew very well hat Mr. Scudamore was spending a great deal more money than had been authorized by Parliament, and the question whether the Treasury knew where he got the money or not is of no particular consequence. He had asked them for more money, and they had replied that it would not be granted until he had made out a full detailed account of capital expenditure.

Now, full and detailed accounts are sometimes annoying and troublesome documents, and when they would show an enormous increase of expenditure beyond all previous estimates, the disinclination to produce them is quite natural.

The British Telegraphs are well managed, and perform the service to the satisfaction of the public. Mr. Scudamore is an intelligent, hard-working and competent Manager, and deserves great credit for the energy which he has displayed in providing so satisfactorily for the public wants. But the cost of running the British Telegraphs is no small item, and when the capital account is once closed and the extensions, reconstructions, maintenance and repairs are charged to working expenses, we are afraid that the annual budget will have to provide for a large deficit in the revenue, or the future facilities will be found to be inadequate to the demand of the public.

Already the capital expenditure amounts to £8,890,000, and there are unsettled claims amounting to over £4,000,000 more, which when paid will swell the cost of the plant to an amount far beyond the original expectations of the Government.

It is scarcely probable that when the capital account is closed that the British Telegraphs will have cost the Government less than $70,000,000.

TESTS OF INSULATORS.

The following tests of insulators were recently made on the lines between Cincinnati and Dayton, Ohio, August 1, 1873. Heavy rain for 15 minutes, extending from Cincinnati to Dayton.

Mileage resistance in ohms.:

Glass	1.830.000
Brooks	2.344.800
Kenosha	3.180.800

July 26, 1873. Raining during whole preceding night. Had ceased at 8 A. M., when test was made:

Glass	3.172.000
Brooks	3.660.000
Kenosha	7.056.000

The above tests show great comparative superiority of the Kenosha over the other forms of insulators in use.

The following test shows the insulating power of the Kenosha pattern during a prolonged rain:

July 19, 1873, the line between Pittsburgh and Crestline (Kenosha insulation) was tested, after 19 hours' rain, and found to have a mileage resistance of 2.250.000 ohms.

There is a little boy, nine years of age, in Shelbyville, Ky., who is described by an enthusiastic correspondent as the champion operator of the United States for his age. We hope he is not compelled to work in the office at his tender years, but is early sent to school during the day and to bed at night. By and by his services will be needed, but not surely until he gets into his teens. Let us spare the infants.

MATHEMATICS FOR NON-MATHEMATICIANS.

By William Paget Higgs, LL.D.

Introductory.

Numerous attempts have been made to interest the general reader in the science of mathematics. Some of these attempts have succeeded and others have failed. A careful study of the cause of failure leads to the observation of a striking similarity in the unsuccessful attempt—and this similarity consists in dealing to excess with abstract ideas. Mathematics is a tool invaluable when applied to the shaping of some end, but it is possible, even upon sharpening, grinding, or adjusting a tool, to waste time. Indeed, in the cutting of rough wood an edge may be too keen. So it is with mathematics, and the reader feels that he is constantly at the grindstone. He may admit that by pre-eminence mathematics is the science of abstraction, but experience has taught him that the greatest good has arisen from its application to concrete methods.

Nor would it be difficult to prove that mathematicians, by an excessive devotion to the science in its purity (the proper term for its fullest abstraction), have rendered it unpopular. In its transcendental dress the student approaches mathematics with awe, and if bold enough to question, receives its teachings, as Professor Airy has aptly said, "rather with the doubts of imperfect faith than with the confidence of rational conviction." In his "Principles of the Differential Calculus" Mr. Woolhouse observes, with only too much reason, how "it is to be regretted that most of our academical treatises on this as well as other subjects abound so much with complex algrebraic processes, without the slightest traces of logical reasoning to exercise and improve the intellect. We should bear in mind that the simple execution of analytical operations, acquired by dint of practice and experience, is a mere common species of labor, often merely mechanical, whilst a distinct apprehension of the specific object and meaning of the operations, and a contemplation of the clearness and beauty of the various arguments employed, constitute the intellectual lore that gratifies and enriches the mind, and stimulates its energies with an ardor after the investigation of truth."

But it is time we mapped out the chart intended to be followed in these pages. For our purpose we may consider mathematics, under an arbitrary division, into the solution of problems (*a*), in which it is required to ascertain the value of unknown (from the relation which they bear to known) and constant quantities; and (*b*) to the investigation of variable quantities, increasing or decreasing uniformly with regard to other quantities that are constant. When dealing with *a* we are in the dominion of ordinary *algebra;* the consideration of *b* is effected by means of the differential and the integral calculus. From the symbols and signs of operation of ordinary algebra, with the simpler applications of algebra to geometry, and the necessary investigation of the elements of trigonometrical science, we may therefore pass at once to the principles of the calculus, and place the student as early as possible in a position to understand its applications. Subsequently we may proceed to a mutual study of the doctrine of Quaternions.

The scheme is bold, perhaps too bold. Unless we had profited by the labors of many living mathematicians, and of many who had passed away, it would have been impossible. We lay no claim to originality. On the contrary, aid has been freely taken from every source. The absence of originality is no loss to the student—he is a gainer by the weight of the authorities consulted.

Finally, I have not attempted technicality in language, except where the technical term is self-explanatory; but I have preferred a familiar style, both in language and illustration. In any instance where I may fail to express clearly my meaning, I shall be glad, through the columns of the Journal, to give fuller explanations.

Division I.—The Algebra of Constant Quantities.

Symbols and Signs of Operation.

In arithmetic we have learnt to consider two kinds of numbers, *abstract* and *concrete*. 1, 2, 3 or 4, etc., is an abstract number, because it denotes an abstract idea of how many times; but 1 apple, 2 apples, or 3 apples, etc., is a concrete number, because it denotes so many actual substances. We cannot see or feel 2 as a number until it is embodied in the form of 2 apples.

In algebra, however, the division into concrete and abstract need not be a source of trouble, for we may substitute a *letter* (a, b, c . . . x, y, z) for either an abstract or concrete number. Thus a may be put to represent 1 or 1 apple, or 2 or 2 apples. If a be taken as a kind of short way of writing one apple, $2a$ will stand for two apples; but if a is taken to represent two apples, then $2a$ will stand for four apples, and so on. Similarly, if a be taken to represent the figure 1, then $2a$ will be equal to 2. If a stand for 2, then $2a$ will equal 4.

This is enough, perhaps, to enable the student to understand the definition:—*Algebra is the Science of Computation by Symbols.*

The symbols generally employed are letters of the alphabet, sometimes those of the Greek alphabet. There is no reason why any system of symbols, however arbitrary, should not have been used; but universal custom has given the preference to letters, arbitrary symbols being employed when the number of things or of abstract ideas to be represented exceeds the number of letters.

It will be convenient to remark that there is in common use in algebra a sign for equality, or the words *equal to;* it is=. If we wish to express that one and one make or equal to two, we can write 1 and 1—.

That also there is a sign for addition, called *plus.* and it is + So that we can state shortly 1 added to 1—1, or 1 + 1—2. Again there are signs for subtraction, multiplication and division, to which we must presently refer.

There is some difference between the operations of arithmetic and those of algebra. Instance may be taken in adding 2 and 3. Arithmetically 2 + 3—5; but if we place a for 2 and b for 3, we can only give the result in algebra as $a + b$, unless we previously arrange that c shall equal 5. In the last case we can say $a + b = c$, one of the simplest forms of an algebraic equation. Let us quite understand this. If we have a basket of fruit containing apples (call them a), and blackberries (call them b), we cannot say apples + blackberries equal pears, we can only give the result as fruit, which is a general and not a particular term. Consequently we must be satisfied with the statement of the contents of the basket (if we wish to describe particularly) as being apples and blackberries. Similarly, in algebra, we often cannot describe a more definite result than $a + b$. What does this negative evidence teach? It shows that the sign + is a sign indicating that the action of addition is to be performed—is, in fact, a sign of operation. So are all the signs in algebra; they indicate *what is to be done* when we have found the values of the symbols of letters which they connect. A complete formula, indeed, is nothing more than a symbolic direction to perform certain actions, to attend a desired result, which result may or may not be expressed.

The Equation and the Unknown Quantity.

We have shown how the addition of 3 to 2 and the sum obtained may be shortly written, viz., 3+2—5. This (again taking a for 2, b for 3, and c for 5), it has also been shown, may be represented algebraically as

$$a+b=c.$$

From the *sign of equality* (—) connecting the two members, all similar equal quantities so connected are classed under the general term of an *equation.* The *solution of an equation* or the *solving* of an equation, merely means the working of it out until the *answer* has been found. The *answer* is the *unknown quantity.* The unknown quantity is generally represented by the letter x, or, if there are more than one, by the letters x, y or z (known quantities, as we have said, being represented by the letters a, b, c, &c.)

Substituting, therefore, the letter x for the letter c in the foregoing equation, we have

$$a+b=x \text{ (for the answer).}$$

As we have determined that a shall equal 2, and b shall equal 3, x or the unknown quantity, or answer, must equal 5. Thus we have, as synonymous terms,

$$a+b=x,$$
$$\text{or } 2+3=5.$$

Now we may so ring the changes on the two members of the equation as to form *new* equation. We say *new*, because for *two equations to be equal* (*or to be equated*) *their results* (*or their x's*) *must be equal.*

To test this let us add 2 to *both* sides of the equation. We have

$$1+3+2=5+2, \text{ or } 7.$$

Evidently a new equation, because 5, the former result (or x) does not equal 7. Similarly, if we multiply both sides by 2, or divide them by two, or take two from them, we shall obtain new equations. We learn, then, that the balance of an equation is not destroyed when we treat in any way *both* sides by the same quantity. This is the characteristic of an equation, and from this characteristic there springs a valuable aid to the solution (or finding the answer) to equations.

Let us try to understand its application.

There is a sign employed in Algebra (and sometimes in arithmetic) indicating *subtraction* or *taking from.* The sign is called *minus*, and is —. So that we may state the equation, 3—2=1, or $b=a-x$. Suppose we are told (adhering to our former values for a and b) that

$$a=x-b,$$

and that we are to find the numerical value of x. How should we set about doing it?

Evidently we should say, substituting figures, that

$$2=5-3,$$

or, what is the same thing, 5—3—2. But we wish to know what x is equal to, and to know this it is evident that all we have to do is follow our direction, implied in the equation, to take 3, or b, from the right side of the equation and add to it the left, and so get back our old form—

$$a+b=c, \text{ or } 2+3=5.$$

Or we may proceed in another way, which is, mathematically, the more accurate. We may add 3, or b, to both sides of the equation, thus:

$$a+b=x-b+b,$$
$$\text{or } 2+3=5-3+3,$$

Digitized by Google

and, as subtracting 3 and adding 3 result in nothing, we have again $a+b=x$. This operation of taking from one side of an equation to add to the other, or *vice versa*, the equality being preserved, is termed *transposition*.

We ask our students to set to work and repeat this process for themselves with other numbers. They will derive much greater benefit from such practice than they would from puzzling their brains over the unpractical work even now often given in our text-books. I will make clear what I mean by quoting my lamented friend and former master, Professor De Morgan, who had a vast dislike to the then too common method of illustrating the teaching of algebra by examples of useless equations. "In answer," he says "to a defence sometimes set up, that the system is *practical*, we observe that much of what is done has no reference to any practical end whatever. The great body of the algebraical work of a school consists in questions of multiplication and division which never occur in practice; above all, in the solution of certain *conundrums*, called *problems*, producing equations, of the *practical* nature of which the reader shall judge from the following specimens:

"'A person being asked the hour, answered that it was between five and six, and the hour and minute hands were together. What was the time?'

"'A post is ¼ in the mud, ½ in the water, and 10 feet above the water; what is the whole length?'

"'A person has two horses and a saddle worth £50: now, if the saddle be put on the back of the first horse it will make his value double that of the second, but if it be put on the back of the second it will make his value triple that of the first; what is the value of each horse?'

"Now, if all this be meant for improvement in theory, no one will deny that the reasons of all the rules should be previously understood; but if they be practical questions, we need only say that people have more pertinent methods of answering the question 'What's o'clock?'—that no one concerns himself about the proportion in which a post is shared between wind, water and mud—and that the Newmarket gentry have a better way of determining the value of their horses than by involving them, saddles and all, in a simple equation."

Far be it, however, that we should condemn the general system of teaching; we wish to encourage the disheartened student, who may have succumbed not for want of energy but its waste.

Next we shall have to deal with *negative* quantities, or those quantities erroneously valued as "less than nothing."

Positive and Negative Quantities.

Hitherto we have been dealing with *positive* quantities—that is, with those quantities which are arrived at by counting upwards from zero or 0. But let us imagine ourselves counting *downwards* from zero or 0, and we arrive at so many less than nothing. "Less than nothing," however, as I shall presently endeavor to show, is an incorrect expression. It is convenient to call those quantities above 0 *positive*, and those below 0 *negative*. Positive quantities may or may not have the positive sign (+) prefixed to them, but negative quantities have always the negative or minus sign (—) prefixed. $+a$ is a positive quantity; $-a$ is a negative quantity.

In order to perfectly understand the distinction between positive and negative quantities, we may consider two illustrations:

I have a thermometer, and I plunge it into warm water. The instrument indicates say 20° of heat, and this may be written +20°. Or I plunge the hermometer into a freezing mixture, and the mercury sinks below zero, say 20°; this may be written —20°. 20° of heat is then written +20°, and 20° of cold is written —20°. Now, 20° of cold is not 20° "less than nothing;" indeed, it is a *positive want* of 20° of heat to bring about the normal or zero condition.

The second example will be still more familiar: I *have* three apples, and I may write this as +3 or +3*a*; I *want* three apples, and I may write this as —3, or —3*a*. In the latter case it will take three apples to satisfy my want, and another three apples to make me rich in the amount of three apples.

Thus, —3*a* does not mean three apples "less than nothing," which would be an absurdity, but it means a *want* of three apples to restore my appetite for fruit to its normal state, or state of no desire.

The expression or equation, it will be seen, holds good that—

$$-3a+6a=+3a,$$

for if we take 6*a* as being composed of two 3*a*'s, it will absorb one 3*a* to satisfy the want expressed by the negative or minus sign, and we shall have one 3*a* remaining.

If the reader has mastered the distinction between positive and negative quantities, he has passed the *pons asinorum* of algebra. If he be in possession of the correct meaning, he will understand that the distinction consists in measuring in two different directions—that is, if by + he is told to measure to the right, by — he knows he is to measure to the left. The signs indicate opposition—to add to, and to take from—the possession, and the want of.

That the reader may be assured of his comprehension, let him resolve for himself the following equations:

$$-20+10=-10,$$
$$10-30=-10.$$
$$-2p+6p-4p=0,$$
$$-4p+6p-2p=0,$$
$$6p-2p-4p=0.$$

The last expression leads to the consideration of the mathematical use of *brackets*. Brackets in mathematics are similar in form to the brackets ( ) [ ] of print or of writing, but they do not, as those in print, indicate inferiority or illustration. Mathematically they are signs indicating *collection*. Thus, in the expression

$$6p-2p-4p=0,$$

the repetition of subtraction, indicated by $-2p-4p$ would be equally well represented by $-(2p+4p)$, or by adding the two negative quantities and taking their sum from 6*p*, with the result —0. Brackets are employed to class or collect together several *simple* quantities, which may be taken together as one *compound* quantity. Instead of brackets the *vinculum*, a line drawn above the compound quantity, is sometimes used. Thus the following are identical expressions:

Brackets.	Vinculum.
$6p-(2p+4p=0.$	$6p-2p+4p=0.$

Brackets sometimes occur within brackets, and then the following arrangement is most general:

$$12p-[6p+(2p+4p)]=0.$$

Though simple the reasoning we have followed, the rule for subtraction may be stated even more simply. *Change the signs of all the quantities to be subtracted, and then add.*

Let us test this numerically:

By subtracting a positive number from a positive number, as 4—2=2, and 4+(—2)=2, or rendering a positive number less positive, for in the latter case it takes 2 of the positive number 4 to satisfy the want expressed by the negative sign prefixed to the 2.

By subtracting a negative number from a positive number, as 4—(—2)=6, which is simply a direction to perform the operation of subtracting or removing the *want* of 2—expressed by (—2)—from the 4. We may consider this as a direction to increase a positive number, the direction being written under a negative form.

By subtracting a negative number from another negative number, as —4—(—2)= —2, or, in other words, removing the want expressed by the negative quantity (—2).

By subtracting a positive number from a negative number, as —4—2= —6, or rendering a negative quantity still more negative.

Let us regard the question, which is one of great difficulty, in another light. We know that 4 may be written 4+2—2; for as 2—2 equal nothing, the addition of 0 to 4 does not alter its value. Let us consider subtraction as meaning "taking away," and, starting with 4+2—2=4, let us see the effect of "taking away" first the +2 and then the —2, which is simply a repitition of the examples given above in subtracting a positive or a negative number from a positive number, thus:

Subtraction from a positive number.

4	+2	—2	=4
4	*	—2	=2
4	+2	†	=6

Similarly we may illustrate the two examples remaining, by considering —4 as written —4+2—2, where, as before, 2—2 is nothing.

Subtraction from a negative number.

—4	+2	—2	= —4
—4	+2	†	= —2
—4	*	—2	= —6

* Taking away the positive number.
† Taking away the negative number.

Thus we can perceive the reason for the following *rules for brackets:*

If the sign + be before the brackets the brackets may be removed without altering the value of the expression.

If the sign — be before the brackets, remove this sign with the brackets, and change all the signs of the quantities within the brackets.

BASTET'S BATTERY.

This battery consists of a compound of cupric salt, preferably the sulphate, and of the nitrate of soda or potash, in a solution of the same ingredients in sulphuric acid, to form a liquid compound, and in the employment of nitro-hyposulphate of sodium or potash.

DIAMONDS IN THE ELECTRIC LIGHT.—At the conclusion of Prof. Tyndall's third lecture on "Light," on Thursday, at the Royal Institution, a gorgeous spectacle, which is seldom seen, was afforded to the delighted audience. Mr. Streeter had sent a tray of diamonds, set as necklets and other ornaments, upon which were directed the powerful rays from the electric lamp. The display of color by refraction was superb, while the specks of light reflected from the facets upon the walls conveyed the impression of a star-light night. The brilliancy of well-cut diamonds could hardly have received better illustration.

ACTION OF THE ELECTRIC FLUID ON FLAMES, LIQUIDS AND POWDERY SUBSTANCES.—*Second Note by M. Neyreneuf.*—The writer examined flames containing no solid particles. In pure hydrogen there was a sensible attraction by a negative point; in carbonic oxide and sulphide of carbon the

Digitized by Google

attraction was more marked, and to both points. Alcohol behaves like ordinary gas. Retreat of the flame is most marked with essence of terebenthin (burnt in a lamp). If the electric point be directed normally to the surface of liquids in a conducting cylindrical capsule, an umbilicus is produced for both fluids in water, oil, sulphide of carbon, essence of terebenthin. With badly conducting liquids, if one withdraws the point after having immersed it some millimetres, a liquid cone remains adherent as long as the electricity passes. Few powders give distinct effects. The blue sand used for drying with is best. Either electric point held a little way off produces centrifugal effects, while if the negative point be held very near, there is a centrifugal aspiration. On contact one may, as with liquids, raise and maintain a cone of grains during the passage of the current.

ELONGATION BY MAGNETIZATION.—Prof. Mayer has announced some instructive conclusions from a series of experiments upon magnetism. These experiments were made with a view to investigate the change of dimensions suffered by bars of steel or iron by magnetization. Faraday was the first to discover this temporary elongation of an iron bar when magnetized by passing an electric current around the same, while Prof. Henry, of the Smithsonian Institute, Washington, verified these experiments some ten years ago by means of an apparatus of extreme delicacy. The apparatus employed by Prof. Mayer if also very delicate, and capable of measuring a variation in length of one two-hundred-thousanths of an inch. The bars of iron which suffered an elongation when they were magnetized by passing a current of electricity around them, shortened somewhat when the current was interrupted, but never quite regained their original length. With annealed steel bars the results were the same; but with tempered steel they were quite different. Upon passing a current around these they contracted, and on interrupting the current they contracted still further.

ELECTRO DIAPASON WITH CONTINUOUS MOTION.—M. Mercadier. The author wished to construct an apparatus capable—(1) of dividing time into very small equal fractions; (2) of doing so continuously; (3) of conveniently registering these fractions. The instrument he made is as follows:—A tuning-fork is placed upright, and a small electro-magnet is fixed on a support opposite the face of one of its branches; which, on the other side, has fixed to it an "interruptor style" of platinum wire. The other branch has also a style which registers its movement on a rotating blackened cylinder. Between the branches is a platinum plate on a separate support; and with this plate the interruptor style comes into contact when the branches approach each other. The positive rheophore of a pile is connected with the plate; the negative with the electro-magnet. If now the plate is put in contact with the interruptor style a spark appears, the current passes, the diapason begins to vibrate, and the interruptor style synchronously with it. The distance of the plate is varied till the maximum amplitude of vibration is obtained. Numerical results are cited as showing that the vibrations are synchronous, notwithstanding the intermittent action of the electro-magnet. The amplitude of the vibrations depends on the form of diapason, on the distance of the electro-magnetic poles from it, on the height at which the magnet stands, on the intensity of the current, and on the nature and length of the style. This instrument is said to work very satisfactorily.

PENSACOLA, FLA. FERRY PASS, FLA.

MOLINO, FLA. MILTON, FLA.

PENSACOLA JUNCTION, FLA. BAGDAD, FLA.

Connect with the lines of the WESTERN UNION TELEGRAPH COMPANY at Pollard, Ala.

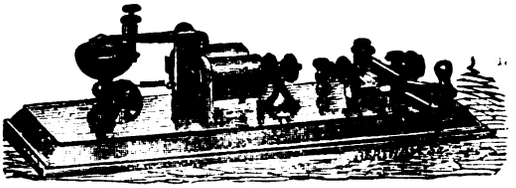
Governed by the same Rules and Regulations as the Western Union Telegraph Company.

WATTS & COMPANY,

Baltimore,

MANUFACTURERS OF

Electrical and Telegraph Instruments



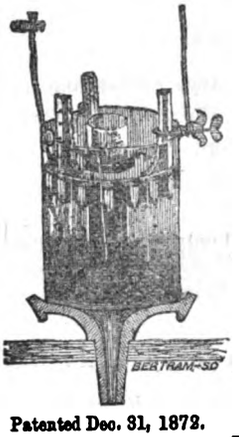
AND

MATERIAL OF EVERY DESCRIPTION,

RELAYS, KEYS, SOUNDERS, COMBINATION SETS, Etc., Etc.

Nickel Plated Goods a Specialty.

A VERY SUPERIOR MAIN LINE SOUNDER.



ENTIRELY NEW.

Furnished in a small black walnut box—which holds pens, pencils, paper, wire, pliers, etc., for opening temporary offices at breaks, etc. It is a complete railroad outfit, and supplies a want which has long existed.

SOLE MANUFACTURERS OF THE

NEW PATENT BALTIMORE BATTERY,

MADE IN THREE SIZES.

Patented Dec. 31, 1872.

No. 1.
Size of Glass, 8x7½ inches,
Specially adapted to Railroad Signals, Printing Instruments etc., etc.

No. 2.
Size of Glass, 8 x 6 inches.
For Locals and Main.

No. 3.
Size of Glass, 7 x 5 inches.
For Light Main.

This Battery is most extensively used throughout the Country having proven the cheapest, and least trouble to maintain of any in the market.

ALSO, SOLE MANUFACTURERS OF THE

Patent Circuit Closer Key,

O'Sullivan Self-closing Key,

Scott's Patent Hotel Annunciator

by which guests telegraph their wants to the clerk, and avoid waiting to have the boy come and see what is required.

ALSO, OF THE

PATENT BATTERY INSULATOR

shown, holding a cup of the Baltimore Battery in the above cut, which most effectually insulates the Battery as the drip passes off *through a hole in the Insulator.*

The Electrician of the Western Union Telegraph Company, Mr. PRESCOTT, says of it:—"I think your Battery Insulator is very admirably adapted for the purpose designed, and it ought to receive general adoption."

Also, ELECTRIC GONGS of all sizes.

RAILROAD SIGNALS.

SWITCH BOARDS, any Pattern.

A CHEAP DIAL INSTRUMENT for Private Lines.

All kinds of BATTERY MATERIAL.

WIRES.—Rubber, Kerite, Silk and Cotton Covered Office—all Sizes.

Insulators.

BROOKS, SCREW GLASS, RUBBER HOOK.

CROSS ARMS, PINS, BRACKETS.

Repairers' Tools constantly on hand.

Importers and Dealers in best English and American Galvanized Wire.

MANIFOLD PAPER, for Train Orders, etc. Also, AGATE PENS.

In fact, everything used in connection with TELEGRAPH LINES we are prepared to furnish, and equip any length of line in the shortest possible time. Having our own Foundry, we can furnish Brass Castings of any description at moderate prices.

Manufacturers and Dealers in

Telegraph Instruments and Supplies

OF EVERY DESCRIPTION,

38 Vesey Street, New York.

New and Superior patterns of

STANDARD TELEGRAPH INSTRUMENTS.

Their RELAYS, SOUNDERS, and KEYS which have been specially designed by Mr. F. L. Pope, are elegantly designed, thoroughly well finished and scientifically adapted to the service required and are recommended as SUPERIOR TO ANY HITHERTO OFFERED.

In addition to these ALL DESCRIPTIONS OF TELEGRAPH MATERIALS AND SUPPLIES are furnished, such as

INSULATORS, BATTERIES,
INSULATED WIRES,
CHEMICALS., ETC, ETC.

MAGNETIC AND DIAL INSTRUMENTS.

We have for sale also THE NONPAREIL TELEGRAPH INSTRUMENT for amateurs, learners and short lines.

A COMBINATION SET, comprising Sounder and Key on a handsome rosewood base.

Bradley's Box Relays and Sounders.

Bradley's Apparatus for Electrical Measurement.

Bradley's Naked Wire Helices and Magnet Spools to order.

any desired size and resistance, at manufacturers' lowest price.

Descriptive Circular and Price Lists forwarded upon application to

F. L. POPE & CO.,

P. O. Box 6010 ***38 Vesey St., N. Y.***

THE LECLANCHE BATTERY CO.

Offer for Sale this celebrated Battery,

(SECURED BY LETTERS PATENT,)

Of which they are the exclusive owners in this country.

Over 300,000 are now in use in Europe,

and have recently been adopted by the French Government in preference to the Calland, which had been used by them for several years.

WE RECOMMEND THEM FOR

Telegraphy (open circuit), Railroad Signals, Hotel Annunciators, Burglar Alarms, Electric Bells, Clocks, &c.

AMONG ITS NUMEROUS ADVANTAGES ARE—

ABSENCE OF ACIDS AND SALTS OF COPPER,

ITS GREAT CLEANLINESS,

WONDERFUL DURABILITY,

ECONOMY IN RUNNING EXPENSES,

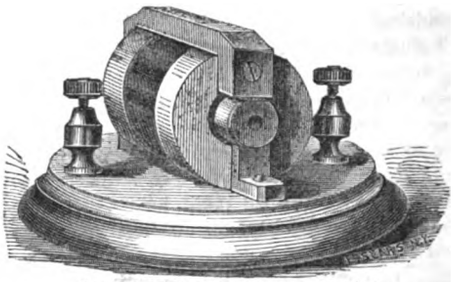
ENTIRE ABSENCE OF ODOR.

This Battery will last without any attention from six months to three years.

A large number of Cups are already in use in this country on Burglar Alarms, Electric Bells, &c., and are giving entire satisfaction. The Western Union has a number of Cups put up November 26th, 1872, that are still running.

For further particulars apply to

THE LECLANCHE BATTERY CO.,



No. 40 West Eighteenth Street.

No. 8 Dey Street, New York.

SOMETHING NEW.

"The Rattler" Telegraph Sounder.

(PATENT APPLIED FOR.)

This is a very simple and effective Instrument, and, as it does not require any spring to draw the lever back, is always adjusted.

PRICE, - - - - $3.50.

L. G. TILLOTSON & CO.,

No. 8 DEY STREET, N. Y.

TILLOTSON'S EXCELSIOR

Telegraph Instrument.

(PATENT APPLIED FOR.)

This apparatus is constructed of the best material, and finished equal to any Telegraph Instrument, and is warranted first class in every particular. It is especially adapted to the requirements of Students of Telegraphy and the operation of Private Telegraph Lines.

Price, complete, Sounder and Key mounted on finely finished, Mahogany Base, with one Cell Hill's Patent Battery, with Chemicals, eight feet of Office Wire, and " Smith's Manual of Telegraphy "	$7 50
Two sets	14 50
Price of Sounder and Key only	6 50
" " " with Cut Out and Lightning Arrester attached	7 50

SEND FOR CIRCULAR.

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 19. NEW YORK, SEPTEMBER 1, 1873. WHOLE NO. 140.

STEARNS'S DUPLEX TELEGRAPHS.

In a previous number of the JOURNAL we gave a description of Stearns' Duplex Telegraph, based on the differential principle. We now describe and illustrate his more recent invention, based on the principle of the bridge or balance. The differential principle consists in the arrangement of a helix composed of two wires of equal lengths and resistances, in such a manner that when a current is sent from the transmitting station it divides in equal portions, and passes through each coil of the relay at such station in opposite directions, thus producing no effect upon the armature, while the current from the distant station passes through one coil only, and thus causes a movement of the armature corresponding to the signals sent.

The bridge method consists in the combination of the receiving instrument or relay, with resistance coils in such a manner that when a current is transmitted from the home station, it passes directly to the line, without passing through the receiving instrument at that station, this instrument responding only to the currents transmitted from the distant station, which permits of the use of any kind of receiving instrument in place of the relay. The principle upon which this apparatus is constructed and operated is that of the Wheatstone bridge or balance, which invention is based upon the observed fact, that when a current is divided between two circuits, which are connected by a cross wire or bridge, no current will pass through the bridge, provided the resistances of the opposite circuits on each side of the bridge are equal, or are in the same ratio to each other.

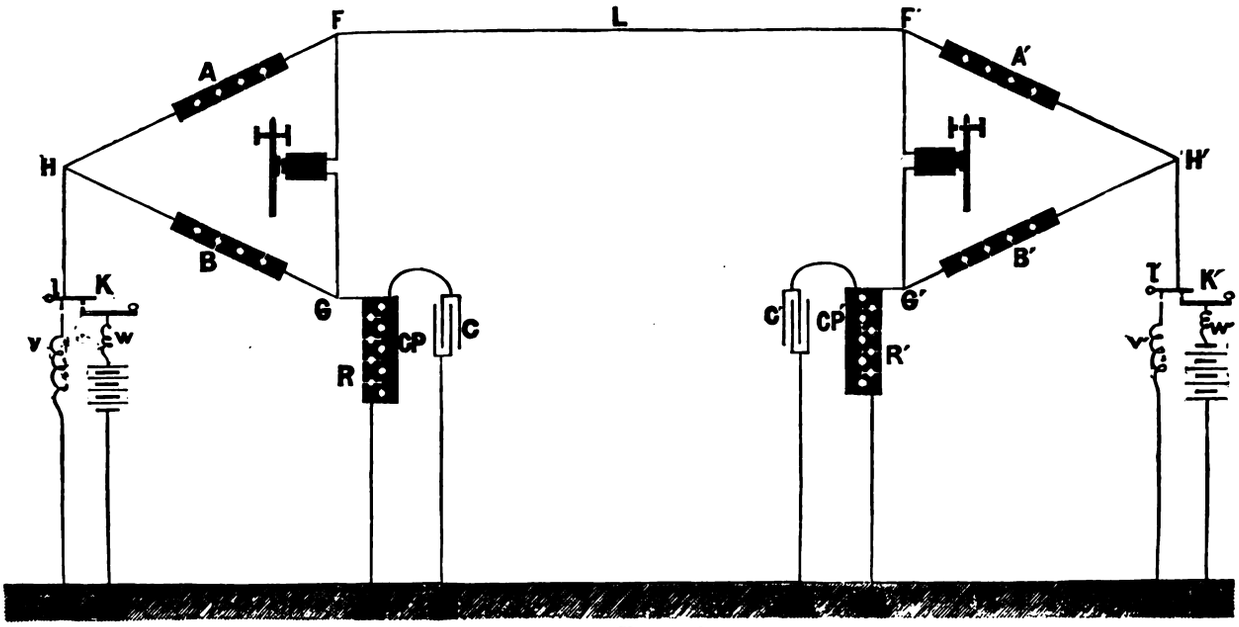

Figure 1.

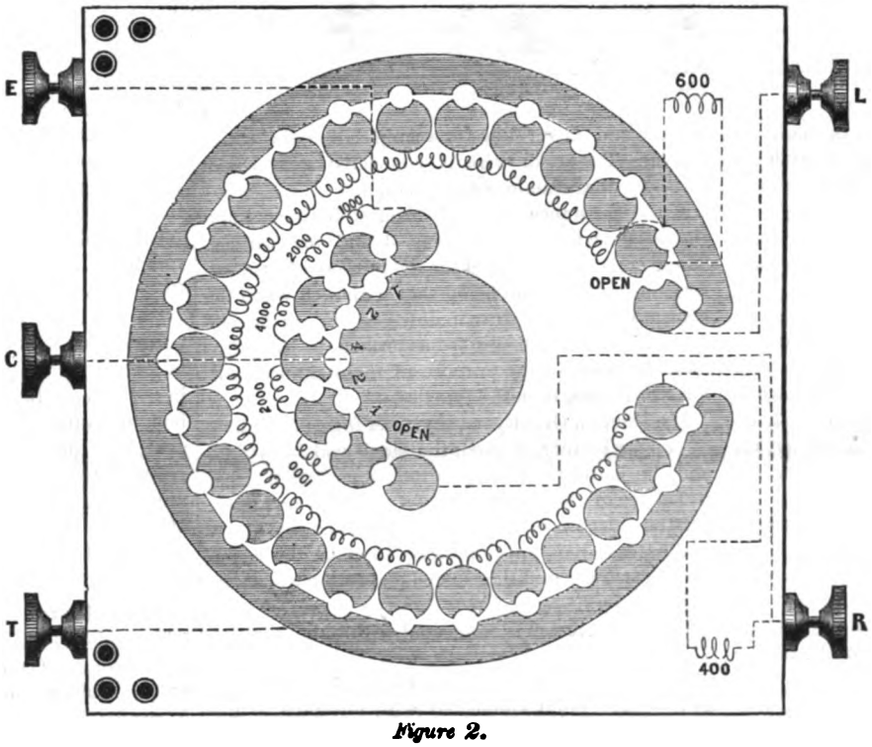

Figure 2.

Figure 1 will serve to show the principle upon which this invention is based. *H*, *A*, *B*, &c., represent the apparatus at one end of a line; and *H'*, *A'*, *B'*, &c., the apparatus at the other end. In this diagram the line *L* constitutes one side of the balance, the resistance coil, or rheostat *R*, the opposite side, while the other two sides are formed by two branch circuits, *A* and *B*. The receiving instrument is placed in the bridge between *F* and *G*. The two branch circuits unite at *H*, and are connected by a wire to the lever *l* of key *K*. When the knob of the key is depressed a current is sent along the wire to *H*, and there branches, a portion passing through the resistance coils *A* to line *L*, and a portion through resistance coils *B* and *R* to the earth.

Now, if the resistance of the circuit *A* and *L* is equal to that of *B* and *R*, no current will pass through the bridge; or, if the resistance of the branch *A* bears the same proportion to that of *L* that the resistance of *B* bears to *R*, then no current will pass through the relay.

For example, suppose the resistance of *A* to be 1,000 ohms, *L* 4,000, *B* 500, and *R* 2,000, then no current would pass through the relay at the transmitting station, because the resistances in the opposite circuits on each side of the bridge are in the same ratio to each other, that of two to one, and consequently, the receiving instrument will be unaffected by the signals transmitted from the home station. When, however, a current from the distant station is put on the line, a portion of it passes through the receiving

Digitized by Google

instrument in the bridge, for, at the point F, it finds two paths to pursue, one through the resistance A to the lever l, and small resistance v or w and battery to the earth, and the other through the relay and coils B and R to earth.

When two or more paths are open to the passage of a current, it will divide itself between them in proportion to their several conductivities.

If the resistance of the relay is 500 ohms, the total resistance of the branch, of which it forms a part, will be $500 + \frac{500 \times 2000}{500+2000} = 900$, and the resistance of the branch $F\,A$ being 1000, the joint resistance of the two branches at F would be $\frac{900 \times 1000}{900+1000} = \frac{900,000}{1,900}$ 473 ohms, which, added to the resistance of the line, 4,000 ohms, would make the resistance of the circuit 4473 ohms. Now, if the electromotive force is 50,000 units, the strength of current at F would be 11.18 units, and this current would be divided between the two branches in proportion to their conductivities (conductivity is the reciprocal of resistance). Thus the conductivity of the branch $F\,A$ would be .0010 and that of the $F\,G\,R$ .0011, and hence 47.62 per cent. of the received current, or 5.32 units, would flow through the branch A to the ground, and 52.38 per cent, or 5.86 units, would flow through the relay to the ground. Of course the amount of current flowing through the relay can be increased or decreased by modifying the resistances in B and R.

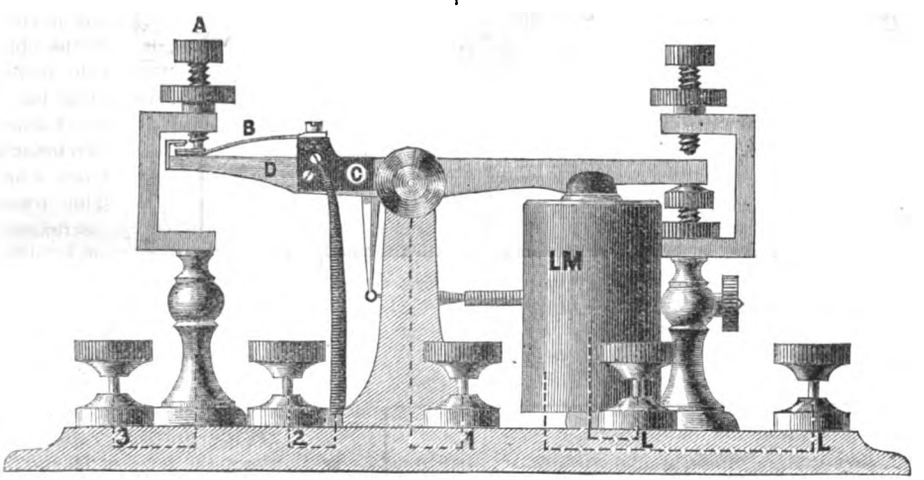

Figure 3.

Key K is so arranged that the line is always connected to the ground, either through the back contact direct, or through the front contact and battery. v and w are small resistances, placed in the circuits to prevent the battery from being put even momentarily on short circuit, and also for the purpose of maintaining a uniform resistance in the circuit when the line is connected to earth direct, or through the battery. C is a condenser, for compensating the static charge from the line, and is attached by a wire to a brass plate, $C\,P$, on the rheostat, R, which is provided with holes for plugs, for connecting it with the resistance coil plates, whereby the condenser charge can be sent through any portion of the resistance coils as desired.

Figures 2 and 3 are illustrations of the apparatus in use by the Western Union Company in the bridge plan.

Figure 2 contains the adjustable resistances, condenser plate and binding screws for connecting the apparatus. The outer circular ring corresponds to the point H in figure 1, and is attached to binding screw T, which is connected by wire with binding screw 2 in figure 3, corresponding with the lever l in figure 1. The discs in the outer circle are connected with resistance coils of 40 ohms each, terminating with resistances of 400 and 600 ohms, respectively, and corresponding with rheostats A and B in figure 1. The discs in the inner circle are attached to resistance coils of 1,000, 2,000, and 4,000 ohms each, corresponding with rheostat R in figure 1, and are connected with binding screw E, which is attached to an earth wire. The large disc in the centre is attached to binding screw C, which is connected with the condenser.

The line wire, and one side of the relay, is connected with binding screw L, and the other side of the relay with binding screw R. By inserting a plug at different points in the series of holes between the outer circle of discs and the circular ring, the two sides of the bridge, corresponding with A and B, figure 1, can be varied at pleasure; and by inserting plugs in the holes between the inner circle of discs, the third side of the bridge, corresponding with rheostat R, in figure 1, can be lengthened or shortened, as desired. By inserting a plug between the inner circle of discs and the condenser plate, any portion of the charge can be sent to line that is desired.

Figure 3 represents the transmitting sounder. L and L are binding screws, for connecting a local battery and finger key for manipulating the transmitter. The earth wire is connected with 1, and one pole of the main battery with 3.

Small resistance coils are inserted between 1 and the earth wire, and between 3 and the battery. These coils are employed for the purpose of preventing the battery from being short-circuited when the transmitting key is drawn down so as to close the front contact, and before it has broken the back contact, and also for the purpose of maintaining a uniform resistance in both branches.

If a Daniell, Gravity, or any other form of sulphate of copper battery, is used, the small coil between 3 and the battery may be omitted, since the internal resistance of the battery offers a sufficient resistance for the purpose of preventing the short-circuiting. In this case it is only necessary to make the resistance between 1 and the earth equal to the resistance of the battery.

Binding screw 2 is connected with binding screw T of figure 2.

$L\,M$ are the local magnet coils; A a set-screw and contact point connected with one pole of the main battery, whose other pole is grounded; D is a lever connected with the earth, and B is a contact point spring, insulated at Q by a piece of hard rubber, and connected as above described with binding screw T of the bridge ring terminal.

By depressing the key of the local circuit the armature is drawn down at $L\,M$, and the spring contact is completed with the contact screw A, and broken with lever D.

The operation of this portion of the apparatus is the same as that of Mr. Stearns's differential plan and need not be further described.

This system has met with great favor wherever it has been tried, and it seems likely to supersede the other form.

When the Duplex is employed in working a cable of considerable static capacity, it is desirable to modify the above condenser arrangement somewhat because the latter discharges so much quicker than the former, and it is necessary to make the discharges of the condensers and cables equal in duration as well as in quantity. If a cable returns, for example, a certain charge, say 10 *m. f.*, a condenser having a capacity of 10 *m. f.* will not produce a balance, for the reason that the condenser discharges so much more quickly than the cable. To make the discharges equal in duration as well as amount, resistance should be introduced between the condenser and the branch circuit.

The following arrangement has been found to work well upon a cable of 18 *m. f.* A resistance of 160 ohms is inserted between the first series of condensers, and the fourth side of the bridge, at the right of point G, figure 1, and a resistance of 50 ohms is inserted between the first and second series of condensers. The first series of condensers returns its charge to the relay through the resistance of 160 ohms, and the second group of condensers returns its charge through the 50 ohm coil, and also the 160 ohm coil. The charge of the second group is retarded slightly more than that of the first group. The 160 ohm coil was wound with one copper wire, but had no iron core, and it was found to retard the charge as much as 250 ohms rheostat resistance. A coil with an iron core would retard the charge much more because the charge current would have more work to do at that point, and a part of it would be converted into magnetism for a while, and afterward reconverted into electricity and continue the current at the last when it is needed. With the above combination the static balance is absolutely perfect, not the slightest quiver of the armature being observable when the circuit is opened and closed. During rainy weather, when a part of the circuit is composed of a land line, it is necessary to remove a portion of the condensers, but not the retardation coils. From the experience obtained thus far it would appear that cables can be worked with Stearns's Duplex with less trouble even than land lines of the same length.

New Electric Pile.—M. Zaliwski, the author, takes two porous cells, one of which fits very loosely in the other. Into the inner cell, containing the carbon, he pours nitric acid; into the other, sulphuric acid; and into the outside non-porous containing-vessel, fitted up with a cylinder of sheet-zinc, a saturated solution of sal-ammoniac. The arrangement of the liquids is, therefore, nitric acid, sulphuric acid, solution of sal-ammoniac.

The traffic receipts of the Eastern Extension, Australasia and China Telegraph Company (Limited), for the five months ending 31st May, 1873, amounted to £86,605, and the month of June to £18,640. The Australian line was opened for traffic in October, 1872. After October next the total receipts for the corresponding period of last year of the three companies recently amalgamated will be published, with the current receipts of the Eastern Extension Company.

ELECTRIC POTENTIAL.

By Fleming Jenkin.

The word potential, introduced by Green, has only lately been generally adopted by electricians, and is still often misunderstood; it expresses a very simple idea, and one quite distinct from the meaning of any other term relating to electricity.

Difference of potential is that difference of electrical condition which determines the direction of the transfer of electricity from one point to another; but electricity cannot be so transferred without doing work, or requiring work to be done; hence the following definition:

Difference of potential is a difference of electrical condition, in virtue of which work is done by positive electricity, in moving from the point at a higher potential to that at a lower potential, and it is measured by the amount of work done by the unit quantity of positive electricity when thus transferred.

The idea of potential essentially involves a relative condition of two points, so that no one point or body can be said simply to have an absolute potential but for the sake of brevity.

The potential of a body or point is used to denote the difference between the potential of the body or point and the potential of the earth.

These definitions require considerable illustration before they can be fully understood.

Electrified bodies repel and attract one another, and, by a slight extension of language, we say that a quantity of positive electricity attracts a quantity of negative, but repels a quantity of positive electricity. If, therefore, we move a quantity of positive electricity towards another similar quantity, we meet with a resistance capable of measurement, equal, for example, to the weight of so many grains. In overcoming this resistance, work must be done, precisely as work must be done to lift a pound or a grain. The work done in moving a body from A to B is measured by the product of the distance multiplied into the force overcome; if the weight of a grain be the unit of force, and the foot the unit of distance, the unit of work will be the foot grain. If, then, in moving a certain quantity of electricity from A to B, we overcome a resistance of ten grains through a space of five feet, we do work equal to fifty foot grains during the operation. On the other hand, the repulsion or attraction of electrified bodies tends to perform work, for the body just brought to B may be driven back to A by the force of electricity alone. In the one case work is said to be done *upon* the electrified body in consequence of its electrification; in the other case, it is done *by* the electrified body in virtue of its electrification; less accurately, we might say the work was done by the electricity, or performed upon the electricity; the measure of the work is the same in the two cases, which are analagous to letting a body fall from the level A to the level B, and raising it up again from B to A.

An electrified body, moving from one point to another, may at one time require work done upon it in order to overcome the resistance; at another part of the journey it may pull in the direction it is going, and then work is done by it. I speak here only of the work done or required in consequence of the electrical condition of the body.

The whole work which has been required, in consequence of electrical attractions or repulsions, to move it from any point A to any point B, will be the algebraic sum of the work done by and done upon the electrified body, the first being called positive and the second negative work.

Thus, in moving the electrified body from A to B, we first had to overcome a resistance, and to do work upon it equal to ten foot grains, whereas, afterwards it pulls towards B, doing work equal to thirty foot grains. Then, in the whole passage from the point A to the point B, the work done by the body may be said to be twenty foot grains. It is true that, during one part of the passage, it did more than this, but only after having required aid previously.

The path followed in going from A to B will be a matter of indifference, so far as the total work done by or upon the body is concerned. We have a precisely analogous case in gravitation—a body of a pound weight, in falling from a height of forty feet to a height of twenty feet above the sea, will do necessarily twenty foot pounds of work in virtue of that fall, no matter what path it follows. We may lift it above A and do work upon it by lifting it before letting it fall, still the whole work done by the body, in its passage from A to B, and in virtue of that fall, will be twenty foot pounds. It may fall by the most *roundabout* or the most direct road, the work done will be the same. It may fall below the level of A and bound up to A; the whole sum of the work will be unchanged, depending merely on the difference of level between the first and second spot. This work may indeed be represented in various ways. Thus, if the body fall direct through a vacuum, the work appears in the form of what is called actual or kinetic energy; that is to say, it is wholly represented by the motion of the mass. If, on the other hand, the body falls slowly, lifting another weight, the work will be represented partly by the weight lifted, partly by the heat due to the friction of the mechanism; but the work done by the body, due to its fall from one level to another, is constant in amount, however various in form.

The work done in overcoming electrical force, or done by electrical force, is subject to the same law.

In moving a weight from a point A to a point B on the same level, no work, on the whole, is either done upon or by the body in respect of its weight; and, similiarly, in moving a small electrified body from a point, A, to some other point, B, it may happen that the point B is so situated that on the whole no work is either done upon or by the body in respect of the electrical forces in action on the body. In that case the two points might be at the same electrical level or height, but the recognized term, in respect of electrical forces, is potential; the points A and B are at the same *potential*. If one small electrified body, for instance, be moved around another large electrified body, neither approaching nearer nor receding farther from it, and so far from all other conductors as not to be sensibly attracted or repelled by them, it will pass along a path every point of which is at the same electrical potential.

In moving any actual body from spot to spot, some work must always be performed to overcome friction, but, as in moving a heavy body from one point to another, at the same gravitation, potential or level, no work is required in respect of its gravitating properties; so, in moving an electrified body from one point to another, at the same electrical potential, no work is required in respect of its electrical properties, although, of course, work will certainly be required to overcome friction, and may be required in respect of gravitaion, if the body be raised, or in respect of inertia, if we accelerate the motion of the mass.

The potential of a body is the excess or defect of its potential above or below that of the earth in the neighborhood, the potential of the earth at that point being arbitrarily assumed as *nil*.

The potential increases in proportion to the increase of work done by any given quantity of electricity in moving from the point to the earth; and, since the potential is proportional to the work and to the quantity of electricity transferred, and to no other quantity, *the potential of a point is measured by the work which a positive unit of electricity does in passing from that point to the earth.*

The unit quantity of electricity might, so far as this definition is concerned, be chosen arbitrarily, but there is a certain convenience for many calculations in choosing the centimetre for the measure of length, and the force capable of giving in one second a velocity of one centimetre per second to a gramme mass for the unit force; this is known as the electrostatic system of units.

Every point everywhere may be said to be at a certain electric potential, just as every point everywhere may be said to be a certain level above or below a datum line, arbitrarily chosen, such as the Trinity high water mark. In speaking of the potential at a point it is as unnecessary to conceive of the presence of any electricity at that point as it is to think of the presence of a heavy body at a point when we speak of its height above the sea.

The electric potential at the point depends on the electrical condition of all bodies in the neighborhood; that is to say, sufficiently near to exercise any sensible force on a small electrified body at the point. Moreover, in testing the equality of the potential at two points by the work done upon or by an electrified body, in its motion from one point to the other, we must remember to choose a body containing only a very small charge of electricity, which we will call the test charge; otherwise, the mere presence of this test body or test charge of electricity would sensibly change the potential at the point at which it was at the time of the experiment increasing, or decreasing for the time being the work which must be done in order to bring any other small quantity of electricity to that point. At first it might appear as if the analogy of gravitation deserted us here, but this is not so; for if I say that two points, A and B, shall, relatively to the earth, be at the same level when no work is done upon or by a heavy body in passing from one to the other, I must remember that, in placing a heavy body at the point A, I do not change for the time the gravitation level of that point, if the body be of sensible size compared with the earth—for its presence at A has increased the attraction of all other heavy bodies to A, so that for the time being a small weight passing from A to B would do work, the position of the centre of gravitation of the earth having been changed.

The *difference of potential* between two points, A and B, being the difference of condition in virtue of which electricity does work in moving from one point to the other, is measured by the work required to move a unit of electricity against electric repulsion from A to B; or, what is the same thing, it is measured by the work which a unit of electricity would do while being impelled from B to A.

The point A is said to have a higher potential than B if a unit of positive electricity, in passing from A to B, performs the work. It is assumed that the unit of electricity does not disturb the distribution of electricity in the neighborhood.

The conception of the work which must be done upon or by electricity, in passing from one point to another, must be grasped as the only idea which can explain difference of potential. Difference of potential can therefore be expressed in foot grains or any other recognized unit of work.

In this paragraph the work is spoken of as being done by the unit of electricity, simply to avoid the awkward periphrasis, "done by a small electrified

Digitized by Google

body charged with one unit of electricity," and "done in consequence of the electric charge only." That is to say, it is the extra work which must be done in moving the body from one place to the other in consequence of its being electrified.

If two electrified conductors, A and B, which are at the same potential, be joined by a wire, no disturbance in the electric distribution on the system will take place, unless, indeed, the wire be of sensible size, relatively to the other conductors, and at a different potential; but, assuming the wire to be small, or at the same potential as A and B, the electricity on the bodies after being joined will be in equilibrium, as before, the necessary condition of equality of potential throughout being satisfied. If, on the other hand, A be at a higher potential than B, positive electricity must, when the connection is made, flow from A to B to reëstablish electric equilibrium.

The amount of electricity thus transferred must be such as will restore the equilibrium; it will be great when the difference of potential is great, and when the size of the bodies is large, and small under the opposite condition.

The magnitude of the conductor has only one influence on the result, by requiring that a larger quantity of electricity shall flow to reëstablish equilibrium. We may illustrate this by an experiment with water. If we join two reservoirs with water, big or little, by a pipe, no flow takes place from one to the other if the surfaces of the water in both are at the same level. If they be not, the flow will take place from the higher to the lower; the quantity of fluid transferred depends on the capacity of the reservoirs and original difference of level; it continues until the level is the same in both. Substitute potential for level, electricity for water, conductor for reservoir, and the above statements are all true for electricity.

By definition, the difference of potential was declared to depend on the work done by or upon electricity in moving from one point to another. The nature of the work done by or upon a quantity of electricity, moved on a conductor by or against a force of attraction or repulsion, is clear enough—a tangible force is used or overcome; a solid body is either put in motion or its motion resisted; but when electricity moves along a wire from a body at one potential to a body at another, no solid body is moved at all, and no equivalent work appears at first sight to have been done. The equivalent is found however, in the heat generated in the wire by the passage of the electricity.

It is well known, from the research of Joule, that 772 foot-pounds of work are equivalent to the quantity of heat which raises one pound of water one degree Fahrenheit, and, although no visible mechanical work is done, when a quantity, Q, of electricity passes along a wire from A to B, heat is generated precisely equivalent in amount to the work which the attractions and repulsions of the electrified bodies A and B would have done when acting upon the same amount of electricity, Q, conveyed on a small moving conductor from the body A to the body B.

Electricity in motion is capable of doing work in other ways, but, in whatever way work or its equivalent is produced by electricity moving from A to B, the amount will always be equal to the quantity of electricity transferred multiplied into the excess of potential of A over B.

Difference of potential may be produced by mere induction, by friction between insulators, followed by separation, or by mere contact of dissimilar conductors. In the latter case the difference of potential is constant with constant materials, *i. e.*, copper and zinc, at a given temperature, touching one another, are invariably at potentials differing by a constant measurable amount. The same may be said of any two metals. Moreover, all metal conductors may be ranged in a list, such that any one of them in contact with any of the conductors later in the list will have a potential positive relatively to that conductor. The exact relative differences of potential have as yet been experimentally ascertained in a few cases.

It is believed that all compound solid bodies which are conductors behave in the same way as simple metallic conductors, so far as the production of a difference of potential due to mere contact is concerned, and this is certainly the case in many instances. Liquid conductors also appear relatively to one another to form a series of the same kind. But compound liquids and solids do not admit of being arranged relatively to one another in the simple order described as applicable to metals.

This difference between the compound liquid and the simple metallic conductor appears to be intimately connected with the fact that electricity, in passing through these compounds, decomposes them. The compounds which are thus decomposed are called *electrolytes*.

The following series of phenomena occur when metals and electrolytes are placed in contact:

1. When a single metal is placed in contact with an electrolyte, a definite difference of potentials is produced between the liquid and the metal. If zinc be plunged in water the zinc becomes negative, the water positive. Copper plunged in water also becomes negative, but much less so than zinc.

2. If two metals be plunged in water (as copper and zinc) the copper, the zinc and the water, forming a galvanic cell, all remain at one potential, and no charge of electricity is observed on any part of the system. (It may be proper to remark that this statement is in direct contradiction to the popular impression.) If the copper (C) and the zinc (Z) had been joined by a metal they would have assumed the same difference of potential as if in direct contact. If, with the two metals, C and Z, plunged in water, a piece of Copper C′ be now joined to the zinc Z, but not in connection with the copper C, C will become positive and C′ negative, the difference of potentials being that due to the direct contact between C and Z only, the water having the effect of simply conducting the charge from Z to C, and of maintaining C and Z at one potential.

3. If a series of galvanic cells be joined up there will be a difference of potentials between the first copper and last zinc equal to the sum of the differences produced by the two joints between zinc and copper; or, taking the difference of potential which a single junction can produce as one unit, the total difference equals the number of junctions. This is Volta's theory of the galvanic battery.

The property of producing a difference of potential may be said to be due to a peculiar force, to which force the name of *electro-motive force* is given. When we say that zinc and water produce a definite electro-motive force, we mean that by their contact a certain difference of potential is produced.

The words *electro-motive force* and *difference of potential* are used frequently the one for the other, but they are not strictly speaking identical. It must be remembered that electro-motive force is not a mechanical force, tending to set a mass in motion, but a name given to the supposed force which causes, or tends to cause a transfer of electricity. Wherever difference of potential is found there must be an electro-motive force; but there are cases in which electricity may be set in motion from one point to another, between which that difference of condition does not exist which we have defined as difference of potential. Electro-motive force is, therefore, the more general term of the two, and includes difference of potential as one of its forms.

Difference of potential or electro-motive force must be measured in terms of some unit adapted to measure work. Every unit of work must be represented by the operation of a force overcoming a resistance, so as to move it through a distance; or, what is the same, it may be represented by the resistance overcome and moved through a distance. In other words, the unit of force exerted through the unit of space is the unit of work. The most common unit of work is the foot-pound, being the weight of a pound overcome so as to be lifted through the distance of a foot, but the so-called absolute unit of work is that which leads to greatest simplicity in electrical calculations. This unit is the absolute unit of force overcoming a resistance through the unit distance, say one centimetre. The absolute unit of work (centimetre, gramme, second) is equal to the foot-pound divided by 13,825 g, where g is the velocity acquired at the end of one second by a body falling in vacuo; taking this as 981 centimetres per second, the absolute unit of work is equal to the foot-pound divided by 13,562,325.

The unit difference of potential, or electro-motive force in electro-static measure, exists between two points, when the unit quantity of electricity, in passing from one to the other, will do the unit amount of work.

The practical measurement of difference of potentials between two points can, in certain cases, be made by observing the work done by definite quantities of electricity in passing from one point to the other; thus we may observe the total amount of heat generated in a wire by a given quantity of electricity passing between two points kept at a constant difference of potentials. From the heat we may calculate the work, and from the heat and quantity we may calculate the difference of potentials. Similarly, if we wished to ascertiain the difference of level between two points, we might let a weight (a standard quantity of matter) fall from one to the other, measure the total heat generated by the concussion which brought the weight to rest, from the heat deduce the amount of work done, and from this work and the known quantity of matter deduce the difference of level or of gravitation potential. Fortunately there are more direct methods available, or engineers would have some difficulty in leveling.

Difference of electric potentials is more generally astertained indirectly by a knowledge of the laws connecting potential with other electrical magnitudes. Thus we know that the quantity of electricity with which two opposing surfaces of conductors are charged is simply proportional to the difference of potential between them, assuming the distance and dielectric to remain constant. Electrometres afford us the means of comparing such quantities as these, and, therefore, electrometres afford us the means of comparing differences of potential.

THE Indo-European Telegraph Company announces that the cable between Madras and Penang, which was interrupted on Sunday, May 11th, having been restored, messages may be again telegraphed direct to Penang, Singapore, China, Japan, Java and Australia, by the lines of this company *via* Teheran. The regular tariff to these places has been resumed, in lieu of the temporarily reduced tariff charged during the interruption.

MATHEMATICS FOR NON-MATHEMATICIANS.

By William Paget Higgs, LL.D.

Division I.—The Algebra of Constant Quantities.

Multiplication, Involution, and Exponents.

Early in our studies we understood that if a be taken as a kind of short way of writing one apple, $2a$ will stand for two apples; but if a is taken to represent two apples, then $2a$ will stand for four apples; and so on. Similarly, if a be taken to represent the abstract number one, then $2a$ will be equal to 2. If a stand for 2, then $2a$ will equal 4. Thus the figure 2 is a multiplier, and all multipliers in similar position are termed *co-efficients*. In the instance given the co-efficient of a is 2, a numerical co-efficient.

Co-efficients are *numerical* and *literal*. If it is understood that n shall represent any determined number, then na will represent n times a, and n will be the literal co-efficient of a.

It is convenient to indicate the operation of *multiplication* by letters placed together as na. This operation is indicated also by the sign × between two quantities, as $a \times b$, or by a point ·,* as $a \cdot b$. Thus ab, $a \times b$, and $a \cdot b$ are identical in meaning.

It will at once be seen how we may indicate multiplication of a bracketed quantity, as—

$$2(a+b)=2a+2b, \text{ or } n(a+b)=na+nb.$$

And how we may obtain a rule for the removal of the brackets when a co-efficient stands before them—that is, when removing brackets, to multiply all the terms of a bracketed quantity by the co-efficient. As instances the reader may trace out the meaning of the following equations:

$$3ab(x+y)=3abx+3aby.$$
$$n(ax+by)=nax+nby.$$
$$a(b+c)\times(d+e)=(ab+ac)\times(d+e)=$$
$$=abd+abe+acd+ace.$$

We have learnt that a *co-efficient* is a *multiplier*. It is a common error arising from want of accuracy in limiting the meaning of words, to call a constant quantity that is to be added, subtracted, or to be a divisor, by the name of a co-efficient. Such a quantity is more conveniently termed a *constant*. In the expressions $x+c$, $x-c$, c is a constant; in the expression cx, c is a co-efficient.

The idea of multiplication includes the multiplication of quantities having like and unlike signs—that is, we may be called upon to perform the operation of multiplying a positive quantity by a positive quantity, a negative quantity by a positive quantity, and conversely. The multiplication of a positive quantity by another positive quantity will clearly result in a positive product.† But the result of multiplying together two negative quantities, or a negative and positive quantity, is not so apparent. Let us look more closely at the question.

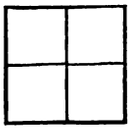
There are four possible cases of multiplication, viz.:

$$a \times b,$$
$$-a \times b,$$
$$a \times -b,$$
$$-a \times -b.$$

The first two are easily understood. In the first case we take a in the number of times represented by b; in the second case we take $-a$, b times. That is, if a is equal to 2, and b represents 3, then $a \times b$ is equal to 6, and $-a \times b = -$, or -2 repeated three times. In the third case, where a is to be multiplied by $-b$, we are directed by the sign of operation to repeat a the number of times represented by $-b$, and as we may always reverse the process and repeat $-b$ the number of times represented by a, the product is again -6. Thus, in both cases where the quantities have *unlike* signs, the product is a minus or negative quantity.

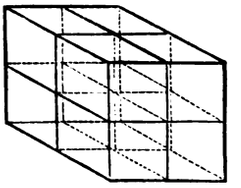
The remaining case of like signs (that of multiplying two negative quantities) it is not so easy to grasp. We must arrive at the result indirectly. The question, numerically stated, is to multiply -2 by -3. If we increase the multiplier (-3) by 4, making it equal $+1$, the product ($--2$) will, of course, be four times too great, and to arrive at the true result we must subtract (4 times -2), or -8. Now, $-2-(-8)$ is, as we have seen when studying subtraction, equal to $+6$.

We have thus arrived at the conclusion, which may be stated as a rule, that the multiplication of quantities having like signs gives a positive product, and the multiplication of quantities having unlike signs gives a negative product. Professor Young concisely states the rule.



Like signs give PLUS; *unlike signs*, MINUS.

Involution and Exponents.



If we desire to multiply a by itself, we may state the result as aa, and repetition of the operation would give aaa. Custom has, however, established a more convenient expression than aa or aaa, namely, a^2 or a^3.* The small figure ^{2} or ^{3} is termed the *exponent*. An exponent shows the number of times a quantity is to be multiplied by itself, or, in technical phraseology, the "power to which the quantity is to be raised." The first power of a given quantity, or a^1, is equal, of course, to the quantity itself. The second power of a given quantity, or a^2, is termed the "square" of that quantity. The third power is termed the "cube." Other powers are known by their ordinal names. The exponent of a *power* must be an integer or whole number; if the exponent be fractional, it indicates a "root," a matter we shall presently describe. The term "square" is derived from the fact that, if we wish to arrive at the superficial contents, or area expressed in square measure of a given space, we may, by multiplying by itself the linear measure of the side of the space, obtain this area; and if again we multiply this area by the given quantity, we have the expression in cubic measure of the solid contents of the space. When referring to geometrical expressions, we should remember that if we represent a line by a, the square built upon that line will be a^2, the solid or cube built upon the square will be a^3. Thus upon a line of two units length—

if we build a square we have, as result, four square units—

and if upon this square we erect a cube, we have eight cubic or solid units—

Geometricians give to the line, the square, and the cube, the term of "space of one, two and three dimensions," respectively. Space of a fourth dimension would be practically inconceivable.

a may then represent space of one dimension.
a^2 " " " two dimensions.
a^3 " " " three "

To be familiar with these ideas, which are really the result of a false analogy, will be necessary when we wish to study the principles of the Differential Calculus; till then they must remain in abeyance, while we consider the use of Exponents as Logarithms.

Negative Exponents, Roots, and the Use of Exponents as Logarithms.

We have learnt that algebraists agree to write, for the multiplication indicated by xx or $xxxx$, the expression x^2 or x^4. And now let us find out for ourselves the effect, upon the exponents, of the addition, subtraction, multiplication, and division of the quantities x^2, x^4.

$xx+xxxx$ and x^2+x^4, or $xx-xxxx$ and x^2-x^4, is the simplest manner in which we can express the addition and subtraction of these quantities.

But when we multiply x^2 by x^4 the product shows us a wonderful property pertaining to the exponents.* Thus:

$$xx \cdot xxxx = xxxxxx, \text{ or } x^6;$$
$$\text{Or } x^2 \times x^4 = x^6.$$

That is, *multiplying the quantities x^2 and x^4 together is equivalent to adding their indices or exponents*; or, $x^2 \times x^4 = x^{2+4} = x^6$.

If we seek to divide† x^4 by x^2, we shall see that $xxxx$ contains xx the number of times represented by xx; that is, xx must be multiplied by xx to produce $xx \cdot xx$ or $xxxx$; and this is but saying that x^4 divided by x^2, or $x^4 \div x^2$, or $\frac{x^4}{x^2} = x^2$. We learn, then, *that dividing the quantity x^4 by x^2 is equivalent to the subtraction of the index (2) of the divisor from the index (4) of the dividend*; or that—

$$\frac{x^4}{x^2} = x^{4-2} = x^2.$$

Now this subtraction of indices naturally includes the extension of the idea to *negative indices*. For if we reverse the position of the quantities given above we obtain a result with a negative index:

$$\frac{x^2}{x^4} = x^{2-4} = x^{-2}.$$

And again, by extending our view of the meaning of the term index or exponent, we may arrive at some remarkable, and, as we shall presently perceive, very

* To prevent confusion with decimal fractions the dot is not employed in numerical calculation.

† The result of multiplying two quantities is termed the *product*; the result of their addition, the *sum*.

* The reader must not confound this expression with $2a$ or $3a$; $a2$ means a times a; $a3$, a times a times a; but $2a$ or $3a$ means twice or thrice a.

* Index is another term for exponent; plural Indices.

† Division is represented algebraically and arithmetically by the sign ÷, or more generally by writing the quantity to be divided above a short line, and the divisor below the line, as in fractions. Thus, 1 divided by 2 may be written $1 \div 2$, or $\frac{1}{2}$; that is, one-half. Similarly, a divided by b is written $\frac{a}{b}$ or $a \div b$. The result of the division is termed the quotient

Digitized by Google

useful results. x and x^1 we know to be identical in value, so that—

$$\frac{x^1}{x^1} = \frac{x}{x}.$$

But—

$$\frac{x^1}{x^1} = x^{1-1} = x^0.$$

And—

$$\frac{x}{x} = 1.$$

Whence—

$$x^0 = 1,$$

which expression, if the reader will presently return to it, he will perceive to be the reason or proof that the logarithm of unity to any base is zero; and since $a = a^1$ the logarithm of the base of any system is unity.

Following our reasoning, we may say:

$$\frac{x^0}{x^1} = x^{0-1} = x^{-1};$$

but substituting the value obtained above for x^0—viz., 1—we have:

$$\frac{x^0}{x^1} = \frac{1}{x^1}, \text{ whence we learn } x^{-1} = \frac{1}{x^1} \text{ or } \frac{1}{x}.$$

Unity divided by any quantity is the reciprocal of that quantity. $\frac{1}{x}$ is the reciprocal of x, $\frac{1}{2}$ is the reciprocal of 2. So that *a quantity raised to a negative power is equal to the reciprocal of the positive power of that quantity;* or $x^{-n} \frac{1}{x^n}$, whatever number n may stand for. By which we may arrive at the value of a negative power.

As we can have integral or whole positive and negative exponents, so an extension of reasoning will comprehend fractional exponents. Fractional exponents are employed to indicate *roots.*

A *root* is the quantity that produces a *power.* As the second power or square of 2 is 4, so the square root of 4 is 2. As the third power or cube of 2 is 8, so the cube root of 8 is 2.

The radical sign $\surd$ (a corruption of the letter r) is employed to indicate the lowest or square root of a quantity. And similarly $\sqrt[3]{}$ is employed to indicate the cube root, $\sqrt[4]{}$ the fourth root, &c. Thus:

$$\sqrt{4} \text{ or } \sqrt[2]{4} = 2.$$
$$\sqrt[3]{8} = 2.$$
$$\sqrt[4]{16} = 2.$$

Or, substituting for the radical signs fractional exponents, we have:

$$\sqrt{4} = 4^{\frac{1}{2}} = 2.$$
$$\sqrt[3]{8} = 8^{\frac{1}{3}} = 2.$$
$$\sqrt[4]{16} = 16^{\frac{1}{4}} = 2.$$

Now it is clear that we may read $\frac{1}{2}$ as "the second root of the first power," or as "the (first) root of the second power," for the result is the same, viz., 2. And that—

$$x^{\frac{n}{n}} = x,$$

which is but raising a quantity to a power to reduce it again to its radical or root value.

From our reasoning we may deduce the following *resumé:*

That with powers of the same quantity—

To MULTIPLY, *add* the indices.

To DIVIDE, *subtract* the index of divisor from index of dividend.

To find a POWER, *multiply* the index of the quantity by 2 or 3 or (n) the number of the required power.

To find a ROOT, we *divide* the index of the quantity by 2 or 3 or (n) the number of the required root.

Now since every quantity (a or x) may be written under the form a^1 or x^1, these rules will hold good for all quantities, and admit of the general expressions—

$$x^1 \times x^1 = x^{1+1} = x^2.$$
$$\frac{x^1}{x^1} = x^{1-1} = x^0; \quad \frac{x}{x} = 1; \text{ and } x^0 = 1.$$
$$x^2 = x^{1 \times 2} \text{ (or the index 1 multiplied by 2).}$$
$$\sqrt[2]{x} = x^{\frac{1}{2}}. \text{ (or the index 1 divided by 2).}$$

But, says the reader, what is the practical benefit of all this? We reply, that by a very simple appplication of these principles are our sailors enabled more easily to navigate our ships, the naval architects to design them, the engineer to build our bridges, the astronomer to tell us of the movement of other worlds. The application is Logarithms, without which our laboratories, studies, and workshops would indeed be badly off.

LOGARITHMS.

The term *logarithm* is derived from *ogon arithmos* or the *number of ratios.* Thus, between 1 to 10 there is *one* ratio; between I and 100, two ratios; and between 1 and 1000, three ratios of 1 to 10. The definition has been given that "The logarithm of a number (to a given base) is the index of the power to which the base must be raised to give the number."

Thus if $n = b^l$, l is the logarithm of n the given number to the base b. And if $n = 100$, and b, the base, be 10, then $l = 2$: for—

$$100 = 10^2.$$

If $n = 1000$, then $l = 3$; for—

$$1000 = 10^3; \text{ and so on.}$$

In the following table let n = the number for which we wish to find the logarithm; b, the base; and l, the index or logarithm, and we have:

n		b l
1	=	10^{0} *
10	=	10^{1}
100	=	10^{2}
1000	=	10^{3}

That is, the logarithm of 1 is 0,
10 is 1,
100 is 2,
1000 is 3, and so on.

Consequently, for all numbers between 1 and 10 the logarithm or index is a fraction; between 10 and 100, 1 plus a fraction; between 100 and 1000, 2 plus a fraction. These fractions have been calculated, and are to be found in tables,† of which we shall presently give an example.

The logarithm of a number, n, to a base, b, is usually written $\log_b n$; and so if $n = b^l$,—

$$l = \log_b n.$$

If the last b were 2, and the number 8, the logarithm would be 3, and the expression would become—

$$3 = \log_2 8.$$

But, as our notation is founded upon the decimal system, the base of the common system of logarithms is 10, and this being understood the letter b is omitted. Thus the logarithm of 10 is written log. 10—1.

* We see now the meaning of a^{0-1}, or that the logarithm of unity to any base is zero (^{0}).

† Galbraith and Haughton's should be obtained by the student.

THE UNITY OF NATURAL PHENOMENA.

BY M. EMILE SAIGEY.

As a popular introduction to the study of the forces of Nature, according to the prevalent theories of modern science, for which this work was intended, it deals too largely with the speculative aspects of the subject, without presenting it in the light of an exhaustive analysis, and a systematic exposition. It exhibits the general outlines of what may be called the new physics, but is wanting in ample illustrations, and in lucid consecutive details of the principles of recent important discoveries. The author is too intent on the statement of his private individual views to engage in the elucidation of points of general scientific interest. He throws out many fruitful suggestions, but neglects to trace their bearings and consequences. His work, accordingly, shows the stamp of French vivacity, rather than of German profoundness or English logical completeness. For a beginner, its style is too shadowy for a firm and comprehensive grasp, although to a master of the subject it might need many valuable reminiscences. The author's discussion of the properties of the universal Ether affords a fair specimen of his characteristic manner. He assumes that there is but one substance in the material universe, and that this substance is the ether. This ether is the primitive and most subtle element, the tissue out of which the entire universe is wrought. It is diffused throughout the entire material world, enveloping all bodies, and penetrating into their interstices. Ether is composed of atoms which impinge upon each other, and upon neighboring bodies, forming a universal medium which exerts a constant pressure upon the molecules of ordinary matter. The action of gravity, according to the author, is explained by this hypothesis. Bodies, he affirms, do not owe their gravity to an intrinsic force, but to the pressure of the medium in which they are immersed. The motion of heavy bodies is thus resolved into a transformation of the ethereal motions, and gravity enters into the unity which has been shown to connect all physical forces. It is included in the idea of motion with which heat, light, electricity, magnetism, cohesion and chemical affinity are identical. The idea of matter itself, the author maintains, is thus rendered more clear and simple. The basis of the system is the atom of ether. But we cannot conceive that there are two kinds of matter, differing from each other in their essence. Quite as little can we imagine two systems of mechanics. Since there is but one law for motion, there can be but a single essence for matter, and hence the molecules of ordinary matter must be only aggregates of ethereal atoms. The atom and motion thus explain the universe. One kind of atoms compose the physical world. By virtue of a motion communicated to each other by these atoms, they become so grouped and intermingled as to form simple molecules, and all their compounds. It is to one and the same cause that we must ascribe molecular aggregations in the realm of the infinitely small, and in that of the infinitely large, the gravitation of the heavenly bodies. Admitting the ingenious and subtle character of these reasonings, it cannot be said that in the present state of physical science they amount to positive proof. At the utmost, they can only claim to be considered as founded on plausible hypotheses. They are, therefore, out of place, in a manual designed for popular instruction, and occupy room which might better have been devoted to thorough exposition. The unity of force is no longer a matter of doubtful theory, and the analysis of its principles should not be connected with problems of uncertain solution.

THE ANGLO-AMERICAN, FRENCH ATLANTIC AND NEWFOUNDLAND TELEGRAPH COMPANIES.

The Anglo-American, French Atlantic, and Newfoundland Telegraph Companies have been consolidated into one Company under the name of the Anglo-American Telegraph Company, with a Capital of £7,000,000. The following table shows the statistics of traffic under the various tariffs, from July, 1866 to August 1, 1873:

One of the Anglo Company's Cables broke on the 6th October, 1870, and the other on the 30th November, 1870. The tariff was increased on the 12th of December to $15, to reduce the traffic and enable the Company to carry it satisfactorily over the French Cable. The increase of the tariff from $7.50 to $15, 100 per cent., reduced the number of messages 17 per cent., and increased the receipts 57 per cent. One of the broken Anglo Cables was repaired June 4, 1871, and the other June 17, 1871. The tariff was reduced to $10 July 1, 1871.

One of the Anglo Company's Cables broke 11th March, 1873, and the French Company's Cable on 20th April, 1873. Rate increased on the 1st of May to $1.50 per word, to reduce the traffic and enable the Company to carry it over the only remaining Cable. The increase of the tariff from $1 per word to $1.50, 50 per cent., reduced the number of messages 5 per cent., and increased the receipts 23 per cent. The French Company's broken Cable was repaired May 20th, 1873, and although the Anglo Cable remained broken the tariff was reduced June 1st to $1 per word.

The receipts in 1872 were larger than in any previous year, and the Companies paid dividends of twelve per cent, but the serious breakages since have demonstrated that the dividends should have been less and a larger sum put to reserve. It is now clear that under no tariff have the Companies in any one year earned sufficient to pay their shareholders a reasonable dividend on this class of investment and at the same put aside a sufficient fund for renewing and repairing their cables.

DATES.	TARIFF.	*Average No. of Messages per Day.*	*Average Amount per Day.*

The acknowledgment of receipt of any assessment is to be understood as an acknowledgment for all previous assessments:

ACKNOWLEDGMENT OF RECEIPTS FOR ASSESSMENTS 44, 45 AND 46 UP TO AND INCLUDING AUGUST 29TH.

8, 15, 19, 27, 31, 44, 51, 53, 55, 56, 65, 69, 78, 83, 99, 100 103, 106, 111, 114, 122, 133, 154, 156, 158, 160, 164, 171, 176, 177, 182, 201, 202, 213, 215, 227, 230, 232, 238, 242, 246, 248, 258, 319, 357, 359, 360, 362, 364, 366, 382, 398, 411, 412, 414, 418, 425, 428, 429, 441, 451, 453, 455, 457, 476, 484, 490, 494, 495, 496, 497, 498, 499, 500, 503, 504, 505, 506, 507, 508, 511, 512, 515, 546, 555, 556, 557, 561, 562, 566, 573, 575, 586, 590, 592, 597, 602, 617, 618, 630, 648, 652, 659, 660, 661, 667, 692, 700, 701, 710, 717, 723, 724, 728, 729, 730, 733, 743, 776, 780, 781, 782, 783, 785, 786, 789, 800, 802, 804, 808, 809, 813, 823, 836, 838, 841, 871, 897, 901, 905, 906, 920, 926, 927, 929, 930, 932, 934, 944, 949, 954, 955, 956, 957, 959, 960, 963, 964, 977, 979, 980, 991, 992, 1000, 1002, 1014, 1016, 1026, 1030, 1031, 1032, 1033, 1034, 1041, 1047, 1048, 1050, 1061, 1063, 1080, 1098, 1100, 1101, 1104, 1127, 1139, 1141, 1153, 1182, 1190, 1191, 1205, 1208, 1211, 1213, 1218, 1221, 1228, 1234, 1235, 1255, 1256, 1268, 1269, 1274, 1275, 1277, 1278, 1279, 1281, 1283, 1284, 1285, 1286, 1290, 1327, 1333, 1339, 1340, 1342, 1344, 1346, 1348, 1349, 1350, 1351, 1352, 1366, 1375, 1379, 1405, 1406, 1421, 1427, 1428, 1430, 1431, 1439, 1450, 1464, 1465, 1469, 1470, 1471, 1474, 1475, 1476, 1479, 1481, 1485, 1495, 1496, 1497, 1503, 1505, 1513, 1514, 1531, 1546, 1553, 1562, 1563, 1572, 1573, 1576, 1586, 1596, 1598, 1599, 1600, 1601, 1603, 1604, 1605, 1606, 1607, 1608, 1616, 1619, 1620, 1633, 1638, 1639, 1640, 1641, 1642, 1643, 1646, 1649, 1651, 1653, 1654, 1655, 1657, 1667, 1669, 1672, 1673, 1676, 1677, 1689, 1690, 1691, 1692, 1696, 1700, 1701, 1702, 1704, 1712, 1715, 1716, 1729, 1731, 1733, 1737, 1743, 1746, 1747, 1765, 1766, 1767, 1777, 1782, 1785, 1786, 1788, 1789, 1790, 1802, 1805, 1806, 1810, 1818, 1825, 1828, 1829, 1830, 1832, 1833, 1834, 1835, 1836, 1837, 1838, 1855, 1856, 1857, 1858, 1860, 1863, 1864, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1888, 1889, 1890, 1891, 1899, 1904, 1918, 1934, 1936, 1937, 1939, 1941, 1942, 1953, 1958, 1962, 1963, 1972, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1991, 1992, 1993, 1995, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2012, 2013, 2020, 2022, 2028, 2037, 2050, 2051, 2053, 2054, 2055, 2056, 2061, 2068.

No. 44.—1209, 1631, 1909.

No. 45.—1289, 1647, 1666.

The notices of assessment covering the death of Robert S. Fowler, who died at Dubuque, Ia., July 21; and that of William P. Trites, who died at Monroe, La., 29th ult., will be sent out on Sept. 1st.

The following additional agents have been appointed:

L. C. Baker, Little Rock, Ark.
H. E. Doolittle, La Fayette, Ind.
S. K. Rupley, Poughkeepsie, N. Y.
T. D. Scanlon, Port Hastings, C. B.
P. Bruner, Wellsville, O.

Members are reminded of the Annual Meeting of the Association, which will be held in New York on Wednesday, November 5th. It is exceedingly desirable that as many as possible of the members, and especially of the agents, should be present, as business of vital importance will be brought before the meeting.

BORN.

BOK.—At Brooklyn, N. Y., August 24, 1873, a son to William J. H. Bok, Translator of Languages to the W. U. Tel. Co., 145 Broadway, New York City.

FARRELL.—At Virginia, Nevada, August 12th, to James F. Farrell, W. U. Tel. Co., a son.

HARTMAN.—To J. P. Hartman, Manager W. U. Tel. Co., Alburtis, Pa., a daughter, on the 27th of July, 1873.

MELLEN.—At Smithson. Mo., August 11th, 1873, to J. H. Mellen, Manager W. U. Tel. office, a son.

WILEY.—At Springfield, Ill., August 12th, 1873, to F. P. Wiley, a son.

MARRIED.

ALLEN—DONOHUE.—Sunday, August 24th, 1873, Stewart C. Allen, of Hudson, N. Y., to Miss Alice Donohue, of Bayonne, N. J.

DAVY—ROBERTS.—On Friday, May 23d, 1873, by Rev. R. D. Austin, Mr. Will. H. H. Davy, of Mansfield, Ohio, to Miss May J. Roberts, of Woodburn, Iowa. No cards.

MILLER—SPENCER.—At Georgetown, California, July 30th, 1873, John H. Miller, Manager W. U. Tel. office, to Ella A. Spencer, eldest daughter of Dr. C. G. Spencer.

POPE—DICKINSON.—At Amherst, Mass., Wednesday, August 6, 1873, by the Rev. Mr. Herrick, Frank L. Pope, of Elizabeth, N. J., to Amelia, daughter of Captain M. F. Dickinson, of Amherst.

To the Editor of the Journal of the Telegraph:

Is there any self-adjusting relay now in use that is a perfect success?

We do not know of any.

Digitized by Google

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is over 8,000. It goes to every State, Territory and Province on the Continent. It has become a necessity, and is always welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, SEPTEMBER 1, 1873.

BLANK No. 47 is now printed upon postal cards, and can be obtained from the Supply Department. They should be used exclusively in place of the old form.

MANAGERS are requested to be careful in stating the Number of Messages Sent on blank No. 4, to place the figures opposite the right classification. In very many instances the statement of the Number Sent Collect at Full Rates and the Sent Paid at Half Rates are transposed, and it is of great importance that they should be reported correctly.

QUITE serious losses have been caused through frequent non-observance of that portion of Rule 9 (Book of Rules), which directs that when a part of the tariff is for other lines, the amount for this line should be first stated and then the amount for other lines. A recent case in which the loss would have been prevented if the proper check had been transmitted will serve as an illustration, although the loss was quite as much the result of careless booking and careless service generally. A special press dispatch of 180 words was forwarded collect from a point upon an other line, and transmitted through with the check, 180 collect, only. Through somewhat indistinct figures upon the received copy the clerk carelessly booked it 18 words, and but $3.86 and $6.00 were collected instead of $31.40 and $46.50. The error was developed through the Error Sheets, but too late to collect the difference, more than $40 of which had been paid to another company.

A MANAGER writes to us that, during his absence, his assistant took in and forwarded a half rate message for an office where half rate messages are not received; and that the repeating office through which it passed, forwarded it to its place of destination as a full rate message, subsequently notifying the sending office of his action. The question is now raised as to whether the action of the manager of the repeating office was right in changing the message from a half rate to a full rate, and forwarding it without waiting for instructions from the sending office. We think it was for the reason that the company became responsible for the exercise of due diligence in the transmission of the despatch as soon as it was received from the customer and paid for, and the holding of the message at the repeating office for insufficient tolls might have resulted in a delay rendering the message useless and the company liable for damages. There is no excuse for taking in messages to be sent at half rates to offices where such messages are not received, and any office which commits the fault must bear the consequences. The tariff books are now so complete, and the rules and directions so full and exact, that no office need err as to the proper charges to be made in all cases. Whenever an insufficient amount is collected, however, the message must not be delayed in consequence, as the fault is not with the customer but with the employe who receives the tolls.

AWARD OF THE GREAT MEDAL OF HONOR FOR THE INVENTION OF THE DUPLEX TELEGRAPH.

We recently had the pleasure of inspecting the great Medal of Honor awarded by the American Institute to Mr. J. B. Stearns, the inventor of the Duplex Telegraph. The medal is made of gold, and is beautifully executed. On the obverse, or face of the medal, are representations of the following objects in relief: The Goddess of Liberty, holding a laurel crown in her right hand, and a staff, surmounted by a liberty cap, in her left; the United States Coat of Arms, a spinning wheel, ship under sail, sheaf of wheat, shuttle, horn of plenty, plow and the Caduceus or Mercury's rod, the symbol of good conduct, peace and power. The rod, representing power; the serpents, wisdom; and the two wings, diligence and activity. The reverse of the medal is surrounded by a wreath of oak and laurel leaves, enclosing the following inscription: The Great Medal of Honor, awarded to J. B. Stearns for Duplex Telegraph, 1872.

The honor conferred by this award, so justly bestowed upon Mr. Stearns by the Great American Institute, which occupies so pre-eminently high a position in the metroplis of the Western World, is greatly enhanced by the fact, that only one Great Medal of Honor is awarded by the American Institute during any one year, and none, unless for an invention of paramount importance.

We trust that Mr. Stearns, who is now in Europe, will receive for his great invention as intelligent and substantial an appreciation in the Old World as he has already received in the New.

WE publish in another part of this issue, a table, showing the average daily receipts of the Anglo-American, French Atlantic and Newfoundland Telegraph Companies, under the various tariffs, from the beginning of the operation of the first Cable, July 28th, 1866, to August 1st, 1873. It will be observed that every reduction of the rates from $100 for 20 words, to $16.87 for 10 words, was followed by an increase in the number of messages sent sufficient to maintain and even slightly augment the receipts. The decrease to $10.00, however, was followed by a loss of 23 per cent. in receipts, while a further reduction to $7.50, coupled with the increase in the traffic, caused by the war between France and Germany, was followed by an increase of 100 per cent. in the number of messages and 51 per cent. in the receipts.

Owing to the breaking of two of the cables in the Autumn of 1870, the tariff was increased to $15, in order to reduce the traffic and enable it to be caried over the remaining cable, and resulted in a decrease of 17 per cent. in the number of messages, and an increase of 57 per cent. in the receipts. In the Summer of 1871 the broken cables were repaired, and the tariff reduced to $10 per message, causing an increase of 33 per cent. in the number of messages and a decrease of 6 per cent. in the receipts.

In May, 1872, the rate was made one dollar per word, irrespective of the number of words sent, and was followed by an increase of about 30 per cent. in the number of messages, and of 16 per cent. in the receipts.

Two of the cables were broken in the Spring of 1873, when the rate was increased to $1.50 per word, and resulted in reducing the number of messages 9 per cent., and increasing the receipts 23 per cent. One of the cables having been subsequently repaired and a new one laid, the tariff was again reduced to $1.00 per word, causing a decrease of 34 per cent. in the receipts.

It appears from the results of the operation of these cables for the past seven years, that the reduction in the rates below $1.50 per word does not tend to materially increase the traffic, while it results in a considerable decrease in the revenue. There is a point where the interests of the public and the stockholders are mutually subserved, and if the present rate shall prove to be that point, it will be shown by yielding a sufficient revenue to pay a fair dividend on the investment, and, at the same time, enable the company to put aside a sufficient fund for renewing and repairing their cables.

ONE of the most severe storms ever experienced in Nova Scotia, occurred on Sunday and Monday, the 24th and 25th insts., and the Western Union and Anglo-American lines were very seriously damaged thereby, the wires being badly broken between every two stations all the way from Dorchester to Port Hastings, a distance of 200 miles, and prostrated for miles east of the latter point, the high tide also sweeping the poles and wires into the sea. Crops were ruined, churches blown down, bridges carried away, and hundreds of houses and barns destroyed, and, saddest of all, a considerable loss of life is reported to have resulted from the hurricane, the like of which has not been experienced there for more than half a century.

THE death, after a short illness, of Charles L. Goodwin, superintendent of the Atlantic and Pacific Telegraph Company, has been commemorated by his late associates, in a series of appropriate resolutions which are to be suitably engrossed and forwarded to the widow of their late friend.

DIRECTIONS FOR SETTING UP THE GRAVITY BATTERY.

Place the copper plate in the bottom of the glass jar, and put two pounds of sulphate of copper (blue vitriol) on top of the copper plate. Place the copper frame for holding the zinc on top of the glass jar, and suspend the zinc as near the top of the jar as possible. Fill the jar, within half an inch of the top, with water. If you have any of the sulphate of zinc taken from the porous cup of a Daniell's battery, put a teacup full of it in the jar. If you have none on hand, use about two ounces of sulphate of zinc (white vitriol) for each cup. If you have none of this at hand, use the same quantity of Glauber salt (sulphate of soda), or even common salt (muriate of soda). It is not necessary, however, to use anything but blue vitriol and common water. In this case, the two poles of the battery should be connected together in short circuit for twenty-four hours, during which time it will make its own sulphate of zinc, and will be ready for use.

It is better to put the sulphate of copper, sulphate of zinc and water in the jar, and let them stand until the solutions separate before the zinc is placed in the jar. When the solutions have properly separated, the lower part of the jar will contain a blue fluid, and the upper part of the jar a white or colorless fluid. The zinc should always remain in a colorless solution. In case the zinc is put in the jar before the two solutions of sulphate of zinc and sulphate of copper have separated, the zinc will be coated with a dark substance, and should be taken out and carefully washed.

When the water in the upper portion of the jar becomes saturated with sulphate of zinc, the sulphate crystalizes upon the zinc plate, stopping the action of the battery. The conducting power of a solution of sulphate of zinc is greatest when diluted with an equal quantity of water. Part of the solution should, therefore, be from time to time removed and replaced by water.

When crystals form on the top and sides of the cell, in consequence of the water being charged with sulphate of zinc, they should be removed with a damp cloth. A little grease or fat, rubbed on the sides of the jar, near the top, will have a tendency to prevent the formation of crystals.

When all the sulphate of copper has been decomposed, the action ceases, and sulphate of zinc will be reduced upon the copper plate as a black powder. It is necessary, therefore, to provide a constant supply of sulphate of copper. A few crystals of sulphate of copper should always remain in the bottom of the jar, undissolved.

The jars should not be disturbed when in use, as this would cause the solutions to mix. As the water evaporates from the jar, it should be replenished by a fresh supply.

ANY information relating to C. P. Shelden, formerly an operator at Green River Station, on U. P. R. R., will be thankfully received by John Kurtz, Rockford, Mich.

CHANGES IN THE ALPHABETS.

We have received from Mr. Culley, Engineer-in-Chief of the English Telegraphs, the following letters from two of the oldest telegraph superintendents in England, in relation to the changes of alphabets. The first letter is from the Superintendent of the Midland Railway, and the second from the Superintendent of the London and Northwestern Railway.

Mr. Culley does not like the very high speed manipulation, and thinks the risk of irregular working is increased in far too large a proportion to the extra service done, in which opinion we quite agree:

My Dear Sir: Yours of the 20th inst. received. I recollect the various changes of alphabet perfectly well, but I regret I have no records of the particulars.

If my memory is correct, I do not think the changes caused much, if any, obstruction to business, and certainly not for any lengthened period.

As a matter of course, the clerks are very conservative when they think any contemplated change will give them trouble, and, no doubt, if they are consulted, they will suggest all sorts of imaginary evils.

I have lately converted a number of double needle circuits into single needle circuits on the railway lines, and experienced no great difficulty in changing the system. I give the various stations concerned a sufficient notice of the change about to be made, and provide them with instruments to practice upon, and send teachers to assist them. When the change takes place, the manipulation is not quite so rapid for two or three days, but, with the regular working, proficiency is soon acquired.

I changed the Great Western Double to Single needles without any difficulty, except the disinclination of the men to change.

My Dear Sir: In answer to your inquiry with respect to the changes made in the single needle and printing codes, I beg to inform you that the only difficulty that I remember to have arisen was, that, where there were double needle circuits available, a few clerks did not apply themselves to the learning of the new single needle code, and it was found necessary to slightly reduce their pay, until they were reported competent in the new working.

In making the changes, notice was given that the new code would be in operation from a certain time; and I do not recollect that any delays of a serious character arose, or that many errors were made in consequence of the alteration.

THE ATLANTIC CABLE OF 1865.

NEW YORK, 28th August, 1873.

MY DEAR MR. PRESCOTT:

The "Great Eastern" was, on 20th inst., in lat. 51.58 N. and long. 35.46 W. The weather had been very foggy and boisterous, and, out of twenty days, they had only sixty-nine hours of working weather.

With fine weather, Capt. Halpin has great hopes of being successful in recovering and repairing the 1865 cable.

The cable already picked up was in good condition.

Yours respectfully,

CYRUS W. FIELD.

G. B. PRESCOTT, Esq., W. U. T. Co.

WE are happy to announce the convalescence of Mr. J. C. Hinchman, Superintendent of the Metropolitan District, who has been seriously ill of typhoid fever.

To the Editor of the Journal of the Telegraph:

On Saturday the 19th inst., after a severe thunder shower had passed over the city, and after the lightning had in a great measure ceased, a ball of fire (I can compare it to nothing else), about the size of a billiard ball, rolled into the office upon the wire, and before reaching the arrester it seemed to separate, part of it jumping from the wire and becoming dissipated, as it were, in the atmosphere of the room. The other portion passed through the arrester, burning it slightly and forming a connection between the top and bottom plates of the same, rendering its cleaning necessary afterwards. Thence it passed down the ground wire to the earth, doing no damage to the instruments which were in the circuit at the time. It was not accompanied by any thunder, but made a peculiar hissing or snapping sound, and left behind it a sulphurous smell. Its passage over the wire was slow in comparison to ordinary forms of lightning, allowing us time to observe its movements.

Please explain, through the JOURNAL, the nature, &c., of this form of lightning. Does it emanate from the clouds or the earth? If the former, why was it not accompanied with the usual report of thunder? Is it more or less dangerous than ordinary lightning? K.

Lightning passes from the clouds to the earth, from the earth to the clouds, and from one cloud to another with equal facility. There is but one kind.

The ball of fire you speak of was simply a quantity of atmospheric electricity passing over the wire to the arrester. The wire being over-charged, produced vivid light. The scinctillant appearance was due to fine particles of metal being fused by the intense heat. Its slow motion was an optical delusion. The sulphurous smell was due to ozone, produced by the electric spark.

SHEFFIELD, Ill., August 21st.

To the Editor of the Journal of the Telegraph:

I would like your opinion in regard to the following:

A black message is left for transmission over the W. U. Telegraph Company's lines at 4 o'clock P. M. For some cause the message is not sent until time for half-rate business. The party sending the message comes in office, and finds it has not been sent. He then wants to send the same message at half-rate, and have the balance of the money paid back, he having paid for the first message. Should he be allowed to make the change?

Please answer through the JOURNAL, and oblige G. S. K.

The sender of a message has the right of withdrawing it any time previous to its transmission. If, after having withdrawn it, he chooses to substitute another in its place he clearly has a right to do that also. A message written upon a No. 2 blank, however, cannot be sent at half-rate. All half-rate messages must be written on red blanks.

NEWARK, N. J., Aug. 26, 1873.

To the Editor of the Journal of the Telegraph:

Will you please publish, for the information of those to whom the Callaud Battery is new, that, if they will use the fluids (both blue stone and zinc) of their old Daniell Battery, in constructing the new (Callaud), it will work *strong at once.* This will save time and patience, especially the latter, which is valuable. Z. N. D.

THE Duxbury and St. Pierre cable has been repaired, and is now working.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
September 1, 1873.

To all Offices on W. U. Lines:

The attention of Offices is called to the order in last JOURNAL giving State Rates to and from Offices of the Montreal Telegraph Company in Canada, (*i. e.*, all other line Offices in New Brunswick, Quebec and Ontario.)

It is to be understood that ALL old rates, whether *higher* or *lower* than new State rates are to be discontinued on and after this date.

In the notice of these State rates in last JOURNAL the word "To," printed before the word "Michigan," should have been omitted.

The following changes and additions have been made since the date of the last circular:

GENERAL INFORMATION.

Fort Deposit, Ala., re-opened.

Sargent, Ks., closed. Mail inquiries in relation to checks to Newton, Ks.

Business for Greenupsburg, Ky., will hereafter be sent and checked to Riverton, Ky.

Messages may be taken for Dover, Me., to be sent and checked to Foxcroft, Me.

There are now W. U. offices at Cambridge and Wakefield, Mass., square 21. Check direct. Erase delivery charges.

The office at Lenox, Mass., square 40, printed in Tariff Book, should read Lenox Furnace.

Messages may be taken for Princeton, Mass., and delivered from Worcester, Mass. Charges for delivery, twenty-five cents.

Morgan, Mich., the office on Other Lines, printed in Tariff Book, is in Marquette Co., and Morgans, Mich., square 269, new (W. U.) office in last JOURNAL, is in Newaygo Co.

Como, Miss., closed.

Alexandria, Neb., re-opened, square 513.

Business for the following offices on the B. and M. Line, in Neb., can be sent *via* Lincoln, Neb., at the following rates for Other Lines:

Ashland.....	35 and 3	Waverly	35 and 3
Crete.....	35 " 3	Beatrice.....	50 " 4
Dorchester.....	35 " 3	De Witt.....	40 " 3
Fairmount.....	55 " 4	Juniata.....	105 " 6
Grafton.....	65 " 4	Lowell.....	120 " 6
Omaha Junc....	35 " 3	Harvard.....	80 " 5

Business for Twin Mountain House, N. H., will hereafter be checked direct.

White Mountain House, N. H., closed.

Clayton, N. J., closed.

Farnham, N. Y., closed.

The office at Salisbury, N. Y., square 46, is in Orange Co.

West Bank, Lower Bay, N. Y., changed to Dix Island.

The P. O. A. of Mands, O., is Shoemaker P. O., Butler Co.

Aladdin, Pa., closed.

Canton and Minnequa Springs, Pa., are now W. U. offices, square 93. Check direct.

The P. O. A. of Hillville, Pa., is Monterey P. O., Clarion Co., Pa.

Kinzue, Pa., changed to Ludlow, Pa.

Milford, Pa., closed.

The P. O. A. of Fairview, Butler Co., Pa., is Baldwin, Butler Co., and that of Turkey City, Pa., is "Box 316, St. Petersburg, Clarion Co., Pa."

Messages may be taken for Weissport, Pa., to be delivered from Lehighton, Pa. Charges for delivery, 15 cents.

Bonham, Texas, closed.

Messages may be taken for East Fairfield, Fairfield, Franklin Highgate Centre, Highgate Falls, and St. Albans Bay, Vt., to be delivered from St. Albans, Vt. Charges for delivery, 25 cents, except to St. Alban's Bay, which is $1.50, special delivery.

NEW OFFICES.

266 Stonewall, Ala.

Offices having "Special Sheet A" will check Williamsport, Pa., 30 cents; Gilberton, Frackville and Mahanoy Plane, Pa., 25 cents more than "special rate" to Phila. Square rate not to be increased.

On and after Monday, September 8th, 1873, the following named offices will, unless otherwise specially directed, discontinue the use of all SPECIAL RATES, and adopt instead the Local, Square or State Rates. By "special rates" are meant, all rates at present less than the Local, Square or State Rates.

They will also disregard notices to "Offices having Special Sheet A" in this and succeeding numbers of the JOURNAL.

Other offices, which at present have special rates to any of the offices in this list, will discontinue the use of such rates and adopt instead the Local, Square or State Rates.

ATLANTIC CABLE BUSINESS.

We are notified that the Cable to Spain "*via* Bilbao" is interrupted, messages, therefore, cannot be forwarded from Great Britain by that route.

The Shanghai and Nagasaki Cable is repaired; messages can now be sent direct by telegraph to Nagasaki.

WILLIAM ORTON,
President

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Aug. 21st, 1873.

Referring to instructions published in JOURNAL of March 15th, 1873, in regard to "addresses," the following additional particulars will be observed:

In cases where the sender of a transfer order is unable to give the precise address of the payee, but believes him to be a well-known resident of the place in which the paying office is located, the words "*address known*" should precede the name of the paying office and be counted as part of the message. For example: Pay John Smith, address known, Albany, N. Y.

This rule will also apply to cases where the sender is a regular customer and has made previous transfers to the same payee.

It is expected that an address or an explanation of its omission, as provided in instructions, will accompany every transfer order, and any violation of this rule should be promptly reported to me.

G. H. MUMFORD,
Vice President.

EXECUTIVE OFFICE.
New York, Aug. 27th, 1873.

On and after September 8th money order offices will be established at the following named points:

In R. C. Clowry's District.—Ellsworth, Kas.; Wichita, Kas.; Parsons, Kas.; Mt. Vernon, Ind.; Shawneetown, Ill.

In G. W. Gates' District.—Woodstock, Vt.

G. H. MUMFORD,
Vice President

NEW EXPERIMENTS IN THE DETERMINATION OF THE VELOCITY OF LIGHT.

In a late number of *Nature*, July 3d, a correspondent gives a detailed account—aided by numerous illustrations—of "The new experiments for the determination of the velocity of light." Besides the interest which attaches to these experiments because of the ingenuity of the methods employed, the results obtained are of incalculable value at present, since upon a correct solution of this difficult problem, the success of the approaching transit of Venus observations largely depends. The experiments, to which reference is here made, were conducted by M. Alfred Cornu, of Paris, who, by the aid of perfected apparatus, has overcome various serious objections, and obtained results which may be regarded as final. By M. Cornu's method, a ray of light from a brilliant lamp is sent—after being concentrated by a suitable mirror—between the teeth of a cog-wheel, the revolution of which is effected by clock-work and recorded by electricity. The ray of light, emerging from the openings between the cogs, pass on to a distance of six and a half miles, that is, from the observatory in the Paris Polytechnic School to the barracks on the Valerian Hill. In one of the rooms in these barracks the mirror and collimator were established. The ray, having traversed this space, is reflected so as to bring it back to the point of departure. If the revolving motion given to the wheel is sufficiently rapid, the ray, on its return, meets a tooth in the cog-wheel, instead of an opening, and is, therefore, interrupted. But, if the speed of the wheel be doubled, the returning ray passes through the following opening, and so forth, alternately for increasing rates of revolution. By the aid of a telescope, for observing the ray as it emerges on its return, and an ingenious and accurate electric recorder, the observer obtains all the data needed for future computations. Owing to the lack of clearness in the atmospherc over and surrounding Paris, together with ascending currents of hot air, M. Cornu had great difficulty in obtaining constant results, being forced to make over one thousand experiments, six hundred and ninety of which he calculated. The average thus obtained gave, for the velocity of light, one hundred and eighty-nine thousand three hundred miles (189,300) in a second; by dividing this number by the refractive indices of the air (1,0003), we obtain the number, one hundred and eighty-nine thousand two hundred (189,200) miles in a second in a vacuum; there is a possible error in this value of about one three-hundredth. The Danish observer, Rœmer, from data obtained by calculating the eclipses of Jupiter's satellites, deduced a velocity of one hundred and sixty-seven geographical miles per second. Fizeau, by the aid of an apparatus somewhat similar to that described above, made the rate one hundred and eighty-three thousand miles per second; and Foucault, using a rotating plane-mirror, together with a stationary reflector, deduced a velocity of one hundred and ninety-one thousand miles per second.

A FINE old gentleman, named Plane, died at Belvidere a few days since, at the highly respectable age of 107 years. He was "hale and hearty"—those men who get into the hundreds always are. People were in the habit of betting that he was only 75 years old, such a fine, fresh, youthful character was he. A Chicago newspaper says: "His habits through life were those of temperance and *vactility*." If this is a typographical error, what shall we read for *vactility*? And if it isn't, what, in the name of Noah Webster, is vactility? We ask because we want to live 107 years, be the same more or less.

Connect with the lines of the WESTERN UNION TELEGRAPH COMPANY at Pollard, Ala.

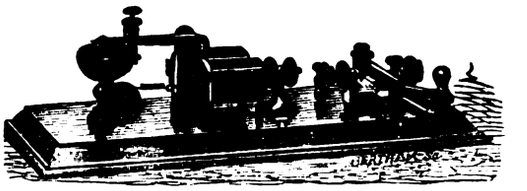
Governed by the same Rules and Regulations as the Western Union Telegraph Company.

WATTS & COMPANY,

Baltimore,

MANUFACTURERS OF

Electrical and Telegraph Instruments



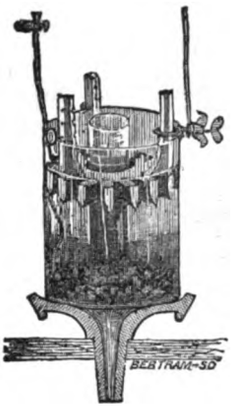
AND

MATERIAL OF EVERY DESCRIPTION,

RELAYS, KEYS, SOUNDERS, COMBINATION SETS, Etc., Etc.

Nickel Plated Goods a Specialty.

A VERY SUPERIOR MAIN LINE SOUNDER.



ENTIRELY NEW.

Furnished in a small black walnut box—which holds pens, pencils, paper, wire, pliers, etc., for opening temporary offices at breaks, etc. It is a complete railroad outfit, and supplies a want which has long existed.

SOLE MANUFACTURERS OF THE

NEW PATENT BALTIMORE BATTERY

MADE IN THREE SIZES.

No. 1.
Size of Glass, 8x7½ inches,
Specially adapted to Railroad Signals, Printing Instruments etc., etc.

No. 2.
Size of Glass, 8 x 6 inches.
For Locals and Main.

No. 3.
Size of Glass, 7 x 5 inches.
For Light Main.

This Battery is most extensively used throughout the Country having proven the cheapest, and least trouble to maintain of any in the market.

Patented Dec. 31, 1872.

ALSO, SOLE MANUFACTURERS OF THE

Patent Circuit Closer Key,

O'Sullivan Self-closing Key,

Scott's Patent Hotel Annunciator

by which guests telegraph their wants to the clerk, and avoid waiting to have the boy come and see what is required.

ALSO, OF THE

PATENT BATTERY INSULATOR

shown, holding a cup of the Baltimore Battery in the above cut, which most effectually insulates the Battery as the drip passes *off through a hole in the Insulator.*

The Electrician of the Western Union Telegraph Company, Mr. PRESCOTT, says of it:—"I think your Battery Insulator is very admirably adapted for the purpose designed, and it ought to receive general adoption."

Also, ELECTRIC GONGS of all sizes.
RAILROAD SIGNALS.
SWITCH BOARDS, any Pattern.
A CHEAP DIAL INSTRUMENT for Private Lines.
All kinds of BATTERY MATERIAL.
WIRES.—Rubber, Kerite, Silk and Cotton Covered Office—all Sizes.

Insulators.

BROOKS, SCREW GLASS, RUBBER HOOK.
CROSS ARMS, PINS, BRACKETS.

Repairers' Tools constantly on hand.

Importers and Dealers in best English and American Galvanized Wire.

MANIFOLD PAPER, for Train Orders, etc. Also, AGATE PENS.

In fact, everything used in connection with TELEGRAPH LINES we are prepared to furnish, and equip any length of line in the shortest possible time. Having our own Foundry, we can furnish Brass Castings of any description at moderate prices.

OF EVERY DESCRIPTION,

38 Vesey Street, New York.

New and Superior patterns of

STANDARD TELEGRAPH INSTRUMENTS.

Their RELAYS, SOUNDERS, and KEYS which have been specially designed by Mr. F. L. Pope, are elegantly designed, thoroughly well finished and scientifically adapted to the service required and are recommended as SUPERIOR TO ANY HITHERTO OFFERED.

In addition to these ALL DESCRIPTIONS OF TELEGRAPH MATERIALS AND SUPPLIES are furnished, such as

INSULATORS, BATTERIES,
INSULATED WIRES,
CHEMICALS., ETC, ETC.
MAGNETIC AND DIAL INSTRUMENTS.

We have for sale also THE NONPAREIL TELEGRAPH INSTRUMENT for amateurs, learners and short lines.

A COMBINATION SET, comprising Sounder and Key on a handsome rosewood base.

Bradley's Box Relays and Sounders.

Bradley's Apparatus for Electrical Measurement.

Bradley's Naked Wire Helices and Magnet Spools to order.

any desired size and resistance, at manufacturers' lowest price.

Descriptive Circular and Price Lists forwarded upon application to

F. L. POPE & CO.,

P. O. Box 6010 *38 Vesey St., N. Y.*

THE LECLANCHE BATTERY CO.

Offer for Sale this celebrated Battery,

(SECURED BY LETTERS PATENT,)

Of which they are the exclusive owners in this country.

Over 300,000 are now in use in Europe,

and have recently been adopted by the French Government in preference to the Calland, which had been used by them for several years.

WE RECOMMEND THEM FOR

Telegraphy (open circuit), Railroad Signals, Hotel Annunciators, Burglar Alarms, Electric Bells, Clocks, &c.

AMONG ITS NUMEROUS ADVANTAGES ARE—

ABSENCE OF ACIDS AND SALTS OF COPPER,

ITS GREAT CLEANLINESS,

WONDERFUL DURABILITY,

ECONOMY IN RUNNING EXPENSES,

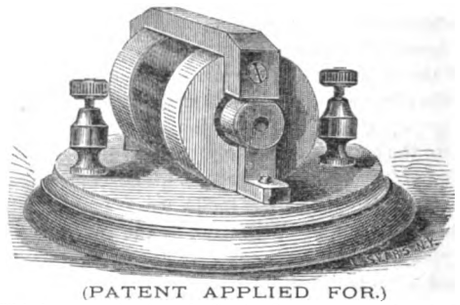
ENTIRE ABSENCE OF ODOR.

This Battery will last without any attention from six months to three years.

A large number of Cups are already in use in this country on Burglar Alarms, Electric Bells, &c., and are giving entire satisfaction. The Western Union has a number of Cups put up November 26th, 1872, that are still running.

For further particulars apply to

THE LECLANCHE BATTERY CO.,



No. 40 West Eighteenth Street.

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 20. NEW YORK, SEPTEMBER 15, 1873 WHOLE NO. 141.

MEASURING INTERNAL RESISTANCE OF BATTERIES.

There are various methods of measuring the internal resistance of batteries.

The Clark method requires a thick wire, or shunted differential galvanometer. The battery is connected in circuit through one-half the galvanometer only, and the deflection noted; it is then connected through both halves of the galvanometer, and resistance added until the deflection is reduced to its first amount: the resistance added will then be equal to the internal resistance of the battery.

For measuring the internal resistance of a battery by this method with the differential galvanometer, manufactured by the Western Union Company, (Fig. 1,) the following method is employed: Connect the positive pole of the battery with C, and the negative with 3, inserting a plug at A, and also in the orifice marked $\frac{1}{100}$ on the left-hand side of the galvanometer. When the key is depressed only $\frac{1}{100}$ of the battery current will flow through one-half of the galvanometer coil, $\frac{99}{100}$ passing through the shunt. The deflection of the needle must be noted. Now, connect the positive pole of the battery with thumb-screw 4, and the negative pole with one end of the rheostat, the other end of which attach to the thumb-screw 3. Insert plugs at both shunts and at A and B. The portion of the current which flows through the galvanometer now passes through both halves of the coil, and the deflection of the needle is consequently increased. Now remove the pegs from the resistance coil until the deflection of the needle is the same as it was when the current passed only through one-half of the coil, and the resistances unplugged will be equal to the resistance of the battery.

The Gaugain galvanometer is admirably adapted to measuring the internal resistance of batteries by the Clark method. As thick wires are used, no shunting is necessary.

The sine or tangent galvanometer may also be used for measuring the internal resistance of batteries. When either of these galvanometers is connected in circuit with a battery, and a certain number of degrees of deflection is obtained, by adding resistance until the sine or tangent of the deflection is reduced one-half, we are certain that the resistence is doubled, and, therefore, that the resistance added is equal to the original resistance. If we deduct, therefore, the resistance of the galvanometer and connections from the resistance added, we shall obtain the resistance of the battery.

The following method was suggested by Sir William Thomson:

Connect in a circuit with the battery, a resistance coil R, and a galvanometer G, and note carefully the deflection; then introduce a second wire S, between one pole of the battery and the other; this will of course weaken the influence of the battery current, and the deflection of the galvanometer will become lessened; now decrease the resistance of the rheostat, R, until the deflection of the needle becomes as great as before, and call the new resistance r; then—

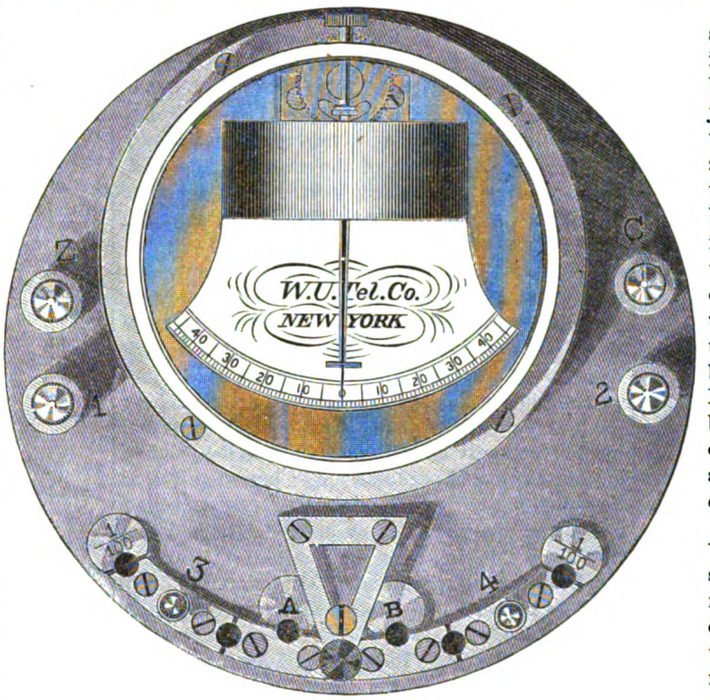

Figure 1.

$$\text{Resistance of battery} = S \times \frac{R - r}{r + G}.$$

The following method may be employed by a galvanometer whose deflections are proportional.

Let D be the deflection obtained with the battery in circuit with a galvanometer, and some resistance r, and d the deflection with some larger resistance R,

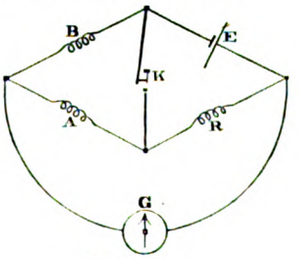

Figure 2.

(the resistance of the galvanometer being included in R and r); and let a=the resistance of the battery.

Then $D : d :: R + x : r + x$,

and $x \frac{(d \times R) - (D \times r)}{D - d}$.

In using this method any other resistance y may be included with x, and the formula becomes—

$$x + y = \frac{(d \times R) - (D \times r)}{D - d},$$

and by deducting x we get the value of y; or, if y be large in comparison with x, the latter may be neglected. By this method one resistance r may be compared with another.

Mance's method consists simply in substituting the battery of which the resistance is to be measured for the resistance in one branch of the Wheatstone bridge, and adjusting the resistances until the needle of the galvanometer which is deflected from zero maintains that deflection constant, when contact at the cross wire of the bridge is made and broken. In the following illustration, (Fig. 2), A, B, E, and R are the four sides of a Wheatstone bridge, K a contact key, G the galvanometer, E being the battery whose resistance is to be measured. Now when AE=BR the resistance becomes determined, or, supposing A and B to be two equal resistances, E and R will be equal. Having placed the battery in one of the branches of the bridge, we make and break contact at K, and if there be no change in the deflection we know that AE=BR, and $E = \frac{BR}{A}$. Practically the result is independent of the galvanometer resistance. It is convenient to give to the constant branches of the bridge a ratio by which the unplugged resistance may be multiplied.

The method admits very easily of experimental proof; for if we make the resistance R great, we shall have a larger deflection when K is open than when pressed down; but if R is small, then when K is pressed down we shall have the larger deflection. Evidently there must be some value for R at which the closing or opening of K does not effect the deflection; and if A and B are equal, this value will be the resistance of E.

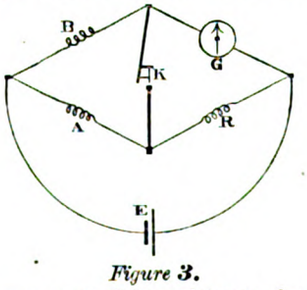

Figure 3.

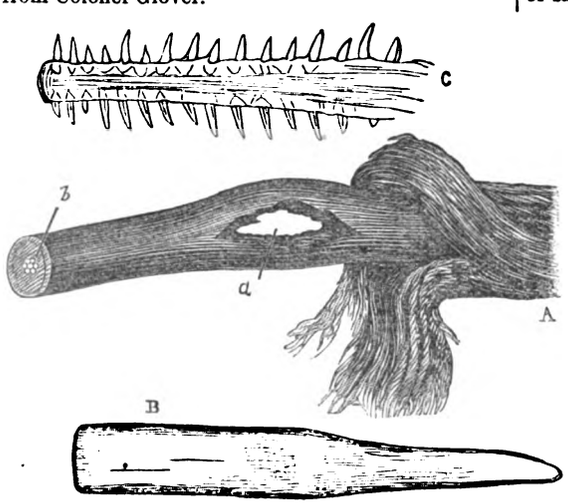
The measurement of the resistance of a battery is difficult, since the resistance is subject to considerable variation during the time of making the measure. And because the constancy of strength of current passing in a circuit is dependent upon the constancy of the resistance of that circuit, many methods

Digitized by Google

which are not cognisant of this variation in strength of current give only doubtful results. In Mance's method the results are to be depended upon, because the variation of strength of battery current does not affect the measurement of the resistance, since all branches are proportionally subject to the variation.

Sir William Thomson has adapted Mance's method for measuring the resistance of the galvanometer when in actual use. The measurement is effected simply by interchanging the galvanometer and battery, as in the next illustration, (Fig. 3.) If AG—BR=O no current will be produced in K, and consequently the deflection of the galvanometer will remain the same whether K be closed or open. When this occurs the resistance of—



$$G=\frac{BR}{A.}$$

Thus the galvanometer is made to measure its own resistance at one constant deflection.

INJURY TO SUBMARINE CABLES.

When submarine cables were first proposed, much trouble was anticipated from the boring of marine animals, through their external envelopes, and thus allowing the water to penetrate to the conducting wires. It was thought, also, that in time, a cable would become covered with adherent mollusks and similar objects, which would be likely to attract fishes and other inhabitants of the sea, the teeth of which might produce serious mechanical injuries. Although such results have not followed to so great an extent as was feared, experience has shown that these apprehensions were well founded. The cable between Florida and Cuba, for instance, is thought to have received serious injury from turtles nibbling at the sea weeds, &c., incrusting it, and we now learn that on one occasion the cable between Singapore and Penang, in the China Sea, became defective, and when taken up, was found to have been perforted by the teeth of a saw-fish, which tore away the coverings, and laid bare the conducting wire.

The accompanying illustration, which is made the actual size of the injured portion of this cable, shows clearly the nature of the injury, and demonstrates in a very satisfactory manner, the truth of the conclusions arrived at, in the following communication from Colonel Glover.

A hempen rope, A, is tightly coiled around the gutta percha portion of the cable. This was, of course, underneath the iron wires which formed the outside of the cable. In the middle of the gutta percha the copper wires are seen embedded at *b*. In the middle of this gutta percha there is a jagged hole, exactly the size and shape of that given in the drawing. A minute observation of the interior of the wound will show that three of the wires at this point are snapped right across, the broken ends being all thrust in the same direction, namely, away from the spectator as he examines the drawing. The remaining four wires (there are seven at the point *b*), however, remain intact. The uninjured wires can be seen at the lower side of the wound, the weapon which made the hole having missed them.

The following information was received from Colonel Glover, R. E.: "The cable was laid on December 11, 1870, and its tests were satisfactory. It worked well until March 1, 1871, or three months afterwards, when a serious fault had developed itself, which prevented working. A vessel went out, found the fault, and repaired it on the 7th June, 1871. The fault was 222 miles from Singapore, and in thirty fathoms water, the bottom being marked sand and mud. The report which came home to us was that a bony substance had been found jammed hard in the cable through the wires, and it was supposed to have been done before laying. As we could not understand why the original tests should be good if the substance had not existed, and why failure should be sudden, I did not believe this; and on receiving the faulty specimen I went to Willoughby Smith, and we opened it together. The bony substance appeared to us as a fish tooth, probably a shark's; but as no mark of the other jaw appeared, we were puzzled, and give it to you. This is all the information we possess, nor, indeed, can get more, as no persons have seen it since."

I confess I was exceedingly puzzled with this most difficult problem. The hole towards the spectator is two-thirds larger than it is on the opposite side. If it had been an ordinary fish, such as a shark, there ought to have been the marks of a bite on both sides of the cable, namely, of a tooth in both the lower and upper jaws. This wound, therefore, must of necessity have been made by a fish having but one tooth, and one tooth only; but what fish is there that has only one tooth? For several weeks I placed the specimen on my mantelpiece, and was constantly thinking over the puzzle. At last one day I hit it off all of a minute. On going round my museum I observed with most intense interest a beak or saw of a sawfish, (*pristis antiquorum*) presented to me by Dr. Day, Inspector of Indian Fisheries, the fish having been taken in the Andaman Islands. "That's the fellow," I said to myself, "that made the hole in Mr. Latimer Clark's telegraph cable;" so, taking one of the teeth out of the beak of the sawfish, I placed a spare portion of the telegraph cable on the table, and struck the end of the tooth with the mallet, and immediately produced a wound almost, I must say exactly, similar to that found on the Penang telegraph cable. This tooth is seen at B.

My theory is very simple, namely, that the perpetrator was a big sawfish. The cable lay at the bottom of the sea, when one day a sawfish came by hunting for his dinner. The sawfish gets his food by waving his saw right and left, turning up the mud or sand in order to dislodge the delicate bodied marine creatures on which he subsists. His teeth will tell us he cannot eat hard substances. When thus engaged in his submarine diggings, he suddenly came across the telegraph cable. His beak getting entangled in it, he gave it an extra blow and a smash downwards, and finally, getting enraged, hit it so hard that one of his teeth went between the outer wires—through the hempen rope—and then through to the gutta percha, injuring the wires. These various substances probably then held the tooth somewhat tightly. The fish then struggled and broke his tooth short off, leaving a bit of it actually imbedded in the cable among the wires.

I am inclined to think that the sawfish uses his formidable weapon to stir up the mud in search of his food, because the points of the teeth in the saw, which are composed of very hard bony substance, are as sharp as the tips of a wild boar's tusk, which are kept finely pointed by constant friction.

RELATION BETWEEN ELECTRICAL AND CAPILLARY PHENOMENA—*M. Lipman.*—When a drop of mercury in a glass vessel, and covered with sulphuric acid, is put in communication with a point of copper or iron passing through the acid, it suddenly becomes more convex, and an electric current is produced which polarizes the surface. The surface contraction is due to a change of capillary constant; this and the electromotive force of polarization are continual functions of each other. Reciprocally, an extension of surface produced mechanically polarizes it as an electric current would. M. Lippman varies the capillary constant of a surface of mercury in a glass tube, by polarizing it with a current from a Daniell element, causing a deformation of the meniscus. He constructs a very sensitive capillary electrometer (for measuring electromotive forces), consisting of a thin glass tube of mercury, which he puts under the object-glass of a microscope for observation of the meniscus as affected by the current. Replacing the pile in the above case by an electrometer or galvanometer, and displacing the mercury mechanically, it can be shown that the electromotive force is varied, the quantity of electricity being independent of the form of the surface, and simply proportional to the area. He also constructs an electro-capillary motor. Two masses of mercury in acidulated water serve alternately as negative electrodes to the current of a Daniell element. In each mass are partially immersed a set of glass tubes open at both ends. At each inversion of the current one set rises, the other descends, and this alternate movement is transformed, by levers, &c., into one of rotation.

MATHEMATICS FOR NON-MATHEMATICIANS.

By WILLIAM PAGET HIGGS, LLD.

DIVISION I.—THE ALGEBRA OF CONSTANT QUANTITIES.

Logarithms (continued).

Before we proceed to the indices of intermediate numbers, we will first apply our deductions to the numbers with which, as logarithms, we are already acquainted.

Logs.	0	1	2	3	4	5	6
Nos.	1	10	100	1,000	10,000	100,000	1,000,000

Rule I.—The sum of the {logarithms / exponents} of two numbers is equal to the {logarithm / exponent} of their product.

Rule II.—The difference of the {exponents / logarithms} of two numbers is equal to the {exponent / logarithm} of the quotient* of these numbers.

Rule III.—The {logarithm / exponent} of the *n*th power of a number is equal to *n* times the {logarithm / exponent} of the number.

Rule IV.—The {logarithm / exponent} of the *n*th root of a number is equal to the *n*th part of the {exponent / logarithm} of the number.

* Or result of division.

Digitized by Google

These rules comprehend the entire use of logarithmic tables, and we will now proceed to their application.

Example to Rule I.—

Log. 100=2
Log. 1,000=3
Log. 100,000=5

$100 \times 1{,}000 = 100{,}000$.

Example to Rule II.—Log. 100=2. Log. 100,000 =5. Five less two =3, and 3 is the log. of 1,000; 100,000 divided by 100 gives 1,000.

Example to Rule III.—The third power of 10 is 1,000. Three times the log. of 10 (or 3 × 1) is the log. of 1,000.

Example to Rule IV.—The cube root of 1,000 is 10. The result of dividing the log. of 1,000 (or 3) by 3 is 1, the log. of 10.

The examples will appear to the student to be self-evident, and it may be thought that logarithms afford only a tedious method of doing what might be more easily done by other rules. But it should be remembered that in practice far more difficult numbers occur than it would be wise to select for illustration.

Having mastered the use of logarithms as integral numbers, we have to deal with the logarithms of those numbers intermediate to 1 and 10, 10 and 100, 100 to 1,000, &c. The logarithms of those numbers between 1 and 10 must, it has been shown, be a fraction less than 1, because the log. of 10 is only 1. Between 10 and 100 the log. of the intermediate numbers is 1 plus a fraction; between 100 and 1,000 the log. is 2 plus a fraction, and so on; because 10 (the base) must be raised to the second-plus-a-fraction-power to give a number higher than 100.

The integral portion of the logarithms of higher numbers than 10 is termed the *characteristic* of the logarithm, and the fractional portion is termed the *mantissa.** In logarithmic tables generally the characteristics are omitted, because it is easy for the calculator to find them by the obvious rule that "*the characteristic of the logarithm of a number is always* ONE LESS *than the number of integral figures of the number.*" This will be seen in the following table of logarithms of numbers from 1 to 20, whence, if we take the log. of 19 (which is 1·27875), we shall find the characteristic† 1 is one less than the number (2) of integers contained in 19.

TABLE OF LOGARITHMS OF NUMBERS FROM 1 TO 20.‡

No.	Log.	Arithmetical Complement.
1	0·00000	0·00000
2	0·30103	0·69897
3	0·47712	0·52288
4	0·60206	0·39794
5	0·69897	0·30103
6	0·77815	0·22185
7	0·84510	0·15490
8	0·90309	0·09691
9	0·95424	0·04576
10	1·00000	0·00000
11	1·04139	0·95861
12	1·07918	0·92082
13	1·11394	0·88606
14	1·14613	0·85387
15	1·17609	0·82391
16	1·20412	0·79588
17	1·23045	0·76955
18	1·25527	0·74473
19	1·27875	0·72125
20	1·30103	0·69897

* A Latin word, meaning an additional handful, something over and above. Plural "mantissæ."

† The characteristic is also termed the index.

‡ We do not include in these lessons an extended or practical table of logarithms, because such a table would absorb valuable space, and is rendered unnecessary by the many excellent pocket and other tables published at a low price.

The student will notice that the log. of 20 is, as far as the mantissa is concerned, the same as the logarithm for 2, and this arises from the fact that 2 bears the same ratio to 10 as 20 does to 100. Similarly the log. of 200 is 2·30103; of 150, 2·17609. He will notice, too, the column headed Arithmetical Complement. The arithmetical complement of a log. is the difference of the mantissa of that log. from unity. The use we shall describe presently. Let us now apply to various examples our four rules previously given.

Rule I. *Example.*—To multiply 90 and 120.

Log. 90 = 1·95424
" 120 = 2·07918
Log. 10800 = 4·03342

A result which the student may verify by reference to a table.

Rule II. *Example*—To divide 418 by 2·4. The log. of 2·4 is 0·38021, the characteristic being 0, because there is only one integer in the number, but the student looks for the log. of 24 in the table.

Log. 418 = 2·62118. The difference between the two logarithms is 2.24097, the log. of 174·16.

It is a law that (as we shall see when we study the subject of division) to divide by any number n is productive of the same result as to multiply by its reciprocal, $\frac{1}{n}$. So it follows that to subtract log. n produces the same result as to add log. $\frac{1}{n} = 0 - \log. n$.

Thus we have a reason for the use of the arithmetical complement. And if we substitute for the log. of the divisor its arithmetical complement, then adding instead of subtracting, we arrive at a similar result.

Log. 418 = 2·62118
A. C. of 2·4 = $\bar{1}$·61979
Log. 174·16 = 2·24097

This step introduces to our notice the expression $\bar{1}$, or that of a *negative* characteristic; and this again leads us to treat of logarithms of numbers less than unity. The logarithm of a fraction or a number less than unity must possess a negative characteristic; for as the log. of 10 is 1, the log of 0·1 or $\frac{1}{10}$ is 10^{-1}, and of 0·01 or $\frac{1}{100}$ or $\frac{1}{10^2}$ is 10^{-2}, according to the rule given which states that "a quantity raised to a negative power is equal to the reciprocal of the positive power of that quantity; or $x^{-n} = \frac{1}{x^n}$, whatever number n may be a fraction. Therefore the log. numbers—

between 1 and 0·1 lies between 0 and —1.
" 0·1 " 0·01 " —1 " —2.
" 0·01 " 0·001 " —2 " —3.
&c.

Hence the following rule:—If the decimal be in the first, second, or third or nth place to the right, the characteristic will be $\bar{1}$, $\bar{2}$, or $\bar{3}$ or $\bar{n}$. Thus, in the tables, the mantissa of the log. of 275 is 0.43933; and—

log. 275 = 2·43933,
log. 27·5 = 1·43933,
log. 2·75 = 0·43933,
log. 0·275 = $\bar{1}$·43933,
log. 0·0275 = $\bar{2}$·43933,
log. 0·00275 = $\bar{3}$·43933.

From this we can clearly understand that the multiplication of a number by any power of 10 affects the characteristic only of the logarithm, and not the mantissa. And from what has gone before it will appear that given a table of the logarithms of prime numbers* it would be easy to calculate all the logarithms of composite numbers.

The calculations with negative indices are made by the rules of algebra. Thus, if it were required to add two of the logarithms given above,—as 2·43933 and $\bar{3}$·43933,—we add first the mantissæ, and obtain 0·87866, and then prefix the result of adding 2 to $\bar{3}$, viz., $\bar{1}$. $\bar{1}$.87866 is the log. of 0·75625. As examples of multiplying and dividing with negative characteristics, we may select the following:—

To multiply $\bar{3}$·43933 by 5.

$$\begin{array}{r} \bar{3}\cdot43933 \\ \times\quad 5 \\ \hline \bar{13}\cdot19665 \end{array}$$

The 2 carried on from the last multiplication of the mantissa is added to the —15, and the result (—15+2) = —13, the logarithm of a very small fraction.

To divide $\bar{13}$·19665 by 5.

The most ready method of division will be to increase the negative characteristic so that it may be an exact multiple of 5, and compensating for the increase, thus:—

$\bar{13}\cdot19665 = \bar{15} + 2\cdot19665$, and this divided by 5 gives $\bar{3} + 0\cdot43933$, or $\bar{3}\cdot43933$.

We may add to these examples illustrations of Rules III. and IV. as to the process of involution and evolution, or the finding of powers and roots by means of logarithms.

Example to Rule III.—Required the 6th power of 18.

Log. 18 = 1·25527
6
7·53162 = log. 34,012,224.

Required the 6th root of 34,012,224.

6)7·53162 = log. 34,012,224.
1·25527 = log. 18.

Next we shall proceed to the consideration of methods of extending the use of ordinary logarithmic tables, and to explain how a system of logarithms calculated to a base, b, may be re-calculated to another base, B.

WORK OF THE ...

...cently issued, giving statistics of new work executed by the Telegraph Department of the Post-office, shows that from the 5th February, 1870, to the 31st March, 1872, a total of 46,146 miles of wire has been erected, 215 miles of underground telegraph laid down (including 23 miles of pneumatic work), and 248 miles of cable submerged. The total number of new instruments brought into use during the same period, less those which have been removed, is 6,421. These figures include private telegraph work.—*London Telegraph, Aug.* 8.

The military telegraph line from San Diego to Prescott and Tucson, Arizona, is being pushed forward vigorously under the direction of the quartermaster and George S. Ladd, contractor. A distance of twenty miles south of San Diego has been completed. The party commenced work last week south of Prescott. There are material and equipment for 630 miles of line on the ground.

* A prime or prime number is a number that cannot be divided except by itself or by unity without remainder; 5, 13, 17, 19, 61, &c., are primes.

CORRESPONDENCE.

To the Editor of the Journal of the Telegraph:

Although the discussion in your excellent paper relative to a change in the telegraphic alphabet of this country has been vigorously progressing for several months, the interest of practical telegraphers in the matter seems in no wise to have abated, but rather to have increased.

This is not surprising, however, for most persons become as much attached to their *mother tongue* as to their native land, and very few, indeed, can contemplate anything like a radical change in the language to which they have always been accustomed without decided aversion.

The phonographers, for example, have demonstrated, most conclusively, that the use of silent letters in the structure of words is productive of more useless toil and perplexity than all other sources of difficulty in written language combined. They have proved to us that the true way to spell or write a word is to put into it as many letters as it contains elementary sounds, and no more; that a written language, to be correct, must contain as many letters as there are rudimental sounds of the human voice; that the scientific way to spell dough is, do; to spell beau is, bo; to spell phthisic is, tizik; and so on through the entire vocabulary.

While nearly every intelligent person is willing to concede that the leading principles laid down by these linguistic reformers are correct, it is, nevertheless, apparent that the *reform* moves but slowly.

It has taken, perhaps, the best part of a century to give ax the preference over axe; harbor, over harbour; savior, over saviour; plow, over plough; yet the tendency to drop the silent or unnecessary letters from words unquestionably prevails, and must, sooner or later, materially simplify and perfect our orthography.

In short, one of the leading and most hopeful characteristics of civilized man is his disposition to correct abuses and imperfections wherever he finds them. It is hoped that the telegraphic fraternity will not prove a solitary exception to the general rule.

The Morse alphabet is the dialect, so to speak, of the American operator. It is his *mother tongue*, and "with all its faults he loves it still."

comes so much ardently love it is certainly but its imperfections, or whether his passion for it be lutely perfect, simply because Prof. M[illegible] of seeing it, he evidently permits his fancy and reverence to run away with his reason.

He might as well insist that the printing press of Johannes Gotenberg was faultless, and fully equal to the wonderful printing machinery of to-day; or that Hans Lippesheim's telescope was as perfect and powerful an instrument as the ones now in use, which unveil the very hills and valleys of the moon; or that the magnificent "floating palaces" now coursing the waters of the globe in every direction, are in no respect an improvement upon the rude steamboat built by Robert Fulton.

That the Morse alphabet is defective in at least one important particular, must be evident to all who have ever had occasion to use it.*

Perspicuity has long been regarded as one of the most essential elements of good composition.

I think it was Quintilian, the great Roman rhetorician, who said that clearness requires, "not that the reader *may* understand if he will, but that he *must* understand, whether he will or not." If this element is so important in the structure of sentences and paragraphs, is it not equally so in the formation of letters and words?

It seems to me that every letter should be so radically different from all other letters, or combinations thereof, as to render a *confusion of characters* utterly out of the question.

As the spaced letters of the Morse alphabet do not possess this requisite, in my humble opinion they should be expunged and perfect ones substituted.

This would involve the learning by telegraphers of six new characters, c, o, r, y, z and &.

Perhaps the following would answer for substitutes as well as any:

c ——·——·, o ———·——, r ——·——·,

y ——·———, z ———··, & ·———·——·

There is not one operator in a thousand who could not learn them all, thoroughly, in less than one month. A large majority would master them inside of a week.

Why worry along with dull tools when sharp ones are within such easy reach. E. J. UDELL.

Rantoul, Ill., Aug. 15, 1873.

To the Editor of the Journal of the Telegraph:

If you will pardon my obtrusion, and allow me space, I would like to offer a few reasons why I do not agree with the author of the article in your issue of July 15th, relative to Telegraphic Instructions in Public Schools. In the outset, while the writer was discussing broad and general principles, no one could object to the fairness and truthfulness of the declarations. But when specially mentioning telegraphy as a branch to be taught in public schools, I feel compelled to enter my feeble protest. The author says telegraphy can be readily acquired by any intelligent scholar, and in the same connection laments, with commendable boldness, the over-production of poor and indifferent operators. Now let us see from past and every day experience if the above-mentioned theory is not destined to swell rather than diminish the circle of incompetent pretenders—frauds I would almost say.

First, I think that it would, from the fact that however easily the first rudiments of telegraphy may be acquired, yet demands of a teacher that which they cannot get at school, that which they can never possess, save in the experience gained in years of thorough, actual application at the desk of a busy even the best [illegible] art of telegraphy, I argue that in public schools than you can more teach it fishermen in some office in New York City, without the very necessary essentials, "brook" and "trout." Think of a man placed for the first time in his life on a locomotive, with all that he can learn from books and teachers at school. Imagine a student graduating from college on Saturday, and on Monday following is intrusted with money and men to locate and prepare for the iron rails, the bed of a railway through some of our hilly countries, where to-day the iron horse is treading. As ludicrous as these illustrations may appear, I offer them as parallel to the idea of teaching telegraphy in our public schools. It appears to me the only proper school for this branch of education is in the office where the business is transacted, where, while the student is progressing in the art they can study all the intricate and perplexing obstacles that are of such frequent occurrence, and must be overcome before the student is competent to engage in the active work, and which never would occur, and could not be easily explained in school.

Suppose each district superintendent, together with managers of offices in his district, select only such candidates as they deem proper, and as many as they need to keep up their force, and give them thorough and practical instructions in their respective offices, receiving therefor proper considerations, and in five years time our ranks would be comparatively free from plugs, and the fraternity at large incalculably benefited. Some of the most important railway lines have adopted this plan, and its good effect is truly magical in driving some who would be failures in the art to where they belong, "chopping cord wood."

AN OBSERVER.

FORT GAINES, CLAY CO., GEORGIA, July 18th, 1873.

To the Editor of the Journal of the Telegraph:

Having read with some interest the communication of Mr. Clayton, of Prairie City, Ill., and that of "Old Member," in the last two numbers of the JOURNAL, in reference to restricting payments to heirs and legatees to one thousand dollars, and feeling considerable interest in that part of our association, I would beg leave to make a suggestion to the committee. Why would it not be a good plan to form Classes A, B and C in the concern, and have and keep just one thousand members (if it can be so arranged) in each class? As fast as its ranks are depleted, both by death and defaulters, add new members, or the last that joined, to it, to keep it full, thereby allowing all who may wish to join all the classes, and secure the advantages for his widow and family at his death. This will give all an equal showing, according to his abilities, to pay up for the different assessments in one or more classes. We would be willing, I dare say, to be taxed 25 cents every three months, to meet contingent expenses—printing, postage, books, and all necessary outlays as are unavoidable.

I think, at a glance, every one would see and know that if he is only a member of Class "A," he would only be assessed for the death of any member of his class only; and instead of raising the initiation fees to $2.50, let it remain at $1.50, as it has always been, and then we would be most likely to always keep all the classes full. Tax us the 25 cents quarterly for necessary purposes: it's but one dollar for twelve months. Many, or I may say nearly all of us, squander five times that amount very foolishly, when, if it was appropriated that way, it may relieve multitudes of suffering. I agree that ours is no scheme for speculation for anybody; but at the same time, if [illegible] by such an arrangement secure to our little [illegible] hence, let us do what we can for the education and maintenance of our dear wife and little ones while we can.

NUMBER 425.

To the Editor of the Journal of the Telegraph:

As most of your correspondents are opposing the change of alphabet, I will say a few words in its favor. I think there is but few that judge, or are able to judge, the result of a change correctly; for how do these opposers know that a change would create such fearful confusion as they are talking of? Have they ever had any experience in the matter, and are they sure that their opposition is not more based upon their individual disinclination of learning the new alphabet, and the little trouble connected therewith, than upon their desire to protect the company and public from disastrous consequences? Any one who has paid attention to the matter can

* The word *rice* furnishes a good illustration:

Is it ryo or rice? . . . . . .

Digitized by Google

see very plainly that there is a considerable part of selfishness in this opposition. I have, since eleven years, changed alphabet three times; but never had I, nor other operators who changed with me, the least trouble in making these changes. There is no use in upholding the spaced letters in the present Morse alphabet. They are doubtless the cause of the greater number of mistakes made in this country, and if the spaced letters are removed there is so much gained. I have used the Continental alphabet for five years, and, admitting that it is longer than the American Morse, I know that it is better than any other that I have seen without spaced letters. I have received thousands of messages with the Continental, in languages which I did not understand, and never to my knowledge made a mistake. This cannot be done with the American, if the sender does not write at a speed which would make the Morse twice as slow as the Continental. The time gained over the Continental alphabet at present could be made up, if private conversation on the various wires would be prohibited.

RAILROAD OPERATOR.

To the Editor of the Journal of the Telegraph:

I am glad to see that the alphabetic discussion is dying out, and a question of still greater importance to the Company introduced. The D. H. and office business is a far more expensive white elephant than spaced letters, and, as your suggestions are not very generally adopted, I want to see an executive order forbidding the use of the wires for comparing check errors, or for sending *free* requests for answers to messages, asking if messages were delivered, &c. I receive several messages (office, of course,) daily of this kind, and in all cases messages are delivered promptly according to contract. Frequently the receivers of despatches are not ready to answer, or prefer to answer by mail, and for this reason office messages are constantly passing over the wires, at the expense of the Company, to "hurry up answer," and sometimes the receiving office furnishes the information *free* what "message was received, and party says will answer by mail!" Our rules are plain enough on this subject: "When a message *cannot* be delivered, the receiving officer must notify the office where the message originated, &c." When an office does *not* receive such notice, he is justified in assuming that the message was received and delivered, and, as I understand it, has no right to send one or more messages free for a party because they paid for the first.

I am not in favor of making operators pay for their own messages, as one correspondent suggests, unless they are of a trivial nature, and of this our officers can judge from the copies sent with free message report. If they think the nature of the business did not justify the use of the wires, make the sender pay full rates, or if it is evident that the message was sent in the interest of a third party—who is not an operator or employee—make the sender pay for it.

In short, we need an order compelling all check error business to be done by mail, and forbidding office messages unless paid for at half rates, as provided for in the rules of the Company, and restricting operators message to their own business of an urgent nature.

OPERATOR.

To the Editor of the Journal of the Telegraph:

I wish to make a suggestion in regard to advertising; or, in other words, letting the public know of the late reduction of rates by the Western Union Telegraph Company. Here we have no means of advertising this, except verbally, and we don't, as a general thing, like the idea of stopping every one we meet and tell them what a sweeping reduction the Western Union Telegraph Company made in rates on July 1st, 1873. I would suggest a neat little calendar, headed Western Union Telegraph Company, and a sheet of heavy ruled paper beneath it, with places to write the names of all prominent and other points local to the town which it may have an office in. Something like the following:

	10 wds.	Each wd. over 10.
To St. Louis, Mo	50	3
" Kansas City	40	3

and so on.

Have one in every merchant's store, and every farmer's house. The people will keep them on account of the calendar and not destroy them. It pays insurance companies to do this, and I can't see why it wont pay a telegraph company.

There are a great many merchants and farmers and mechanics who would use the telegraph if they knew it was so cheap—they have no idea of the cheapness of it. Telegraphing on business, or speculating purposes, is now very much cheaper than mail facilities. A merchant can order his goods by telegraph and have them home in his store, in some cases, before a letter by mail would reach his manufacturer. A great many people would use it socially if they knew it was so cheap. Here in the West nearly every one, farmer and merchant, have their near and dear relatives in the East and South, and in case of sickness would use the telegraph freely, and it would be a great consolation to them. This Company should be advertised in every post office and store and blacksmith shop and schoolhouse in the country.

J. H.

To the Editor of the Journal of the Telegraph:

During a heavy "thunder storm" a question arose among some of the citizens of this place and myself in regard to the danger of having a wire connected with a house. The wire in question is a small "Broom wire," working sounders by local batteries.

I took the ground that it had *little* or *no* attraction for lightning, and that its *capacity* as a *conductor would not be sufficient* to carry a charge of lightning that could injure a building. Admitting that, in the event of lightning coming in *direct contact* with this wire, would not receive only a proportion equal to its capacity as a conductor, and allow the remainder *to escape*, or else be *melted* by the contact. As this, no doubt, is of some interest to many of us, I would like to hear the facts of the case. Approve the tion: Do the latest scientific

R. L. M.

virtue of "lightn

It is not at all likely that the house will be injured by lightning chargeable to the presence of the wire. We have never seen any scientific researches that condemned lightning rods. If lightning rods are properly constructed, and have good earth connections, they are good protection from injury by atmospheric electricity. A telegraph wire attached to a house, is, to the extent of its capacity, a protector, and the greater the number of wires the less will be the liability to injury.

To the Editor of the Journal of the Telegraph:

Suppose I receive a message "Collect," for a man who does not want to pay charges on the same, but wishes to send an answer "Collect,"—should I send the message or refuse until charges are paid on the one received? Please answer in JOURNAL.—E. J. R.

Answer.—You should exact a guarantee in *cash* from such a person. You cannot refuse a message when the rules are conformed with.

To the Editor of the Journal of the Telegraph:

What length of time should the receiver of a message be allowed to answer "Collect" without guaranteeing the same, when no instructions are given by the sending office?

Birmingham, Ala.

Answer.—Not longer than twenty-four hours.

To the Editor of the Journal of the Telegraph:

How many words is "St. James," when it is the name of a steamboat?—a vexed question on our circuit. I claim it is two, based on your decision for St. Albans, Vt., in JOURNAL July 1.

W. G. K.

Answer.—Two words. See Book of Rules, page 10.

To the Editor of the Journal of the Telegraph:

A message was handed me by a customer. I had him read the proper names before I sent it, so as to avoid mistakes, as mistakes and bulls often occur by not understanding the message before the customer leaves. The message handed me contained the word menifee. I asked the customer if it was menifee, or menafee. He said it was menifee. I sent the message as written, and the receiving operator says I bulled it. Now, has an operator a right to change the spelling of any proper name after handed him for transmission; but is it not the duty of the receiver to take as sent? J. A.

Answer.—See rules 7 and 20.—Messages must be sent as written.

G. E. M.—There are twelve words in the following:

"Stewart's note unpaid, and protested; shall I sue?

(Signed) F. M. HOLMES.

Forwarded from Dover, N.H."

B., OPR.—There are eight words in "Lookout for package by fast line this evening."

M. A. TEMPLE.—There are three words in the following message:

To "Charles L. Cole, Assistant General Freight Agent, Pennsylvania Company, Pittsburgh, Pa.

Come without fail.

(Signed) THOS. MCLANAHAN."

The date, address and signature of a message is not charged for. A full address is always desirable to insure quick delivery.

SD.—See reply to "M. A. Temple."

J. SMITH.—There are thirteen words in "C ratchet gear three hundred and so as it is eighty wood mower cod." The Company cannot bably means collect meaning of messages handed may m transmission.

D. J. E.—A knowledge of phonography will avail you nothing as a telegraph operator with the systems of telegraph now in use.

OPR., S. H.—Instead of sending so many office messages, asking—Why no answer, &c., you should have made the customer acquainted with Rule 13, a proper observance of which would probably have afforded satisfaction.

J. HENRY.—We cannot inform you of the different methods in use for train signaling by electricity, nor of the number and names of those patented in this country. We believe that there is a patent log for ascertaining the speed of vessels.

AN OPR.—The proper way to check yourself upon a message destined to a point not upon the lines of the Western Union Company, and which is covered by a frank to the connecting office, would be to enter the amount received in the Total Receipts column, and the same in the column headed Received for other lines, making a note under the head of Remarks.

REX.—A good sound operator can always obtain a good salary. The Superintendent must be consulted as to the precise figures.

C. D. THOMPSON.—Be more explicit.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York.
September 15, 1873.

To all Officers on W. U. Lines:

The following changes and additions have been made since the date of the last circular:

GENERAL INFORMATION.

Hollister, Cal., is now a W. U. office. Erase other line tariff.

Hereafter the "tariff for other lines" to Edwinton, Dac., will be 175 and 12 from Chicago, Ill.

Nameoki, Ill., re-opened; square 348.

Atkinson, Ind., closed.

Until further notice, offices will refuse half-rate business for Shreveport, La.

Old Orchard Beach, Me., closed.

Fort Point, Me., closed.

Hampden, Me., changed to Hampden Corner, Me.

Wenham, Mass., closed.

The rule for counting words in messages to Mexico, directs that words which express amounts should be counted for as many words as it takes figures to express the same. Thus, *one thousand* would be counted as four words—four numerals being necessary to express the amount, one thousand.

Messages for Mexico, however, should be counted as per W. Union rules, but the amount charged for other lines should be sufficient to pay for as many words as the messages contain when counted according to the Mexican rule.

The "tariff for other lines" to Henderson, Minn., is 125 and 8, from Chicago, Ill.

Leaf River, Minn., changed to New York Mine, Minn.

Crookston, Minn., closed.

Sardis, Miss., closed.

Water Valley, Miss., closed.

Georgetown, Neb., closed.

Boars Head, N. H., closed.

Farragut House, N. H., closed.

Sea View House, N. H., closed.

Ocean Grove, N. J., closed.

Harford Mills, N. Y., re-opened.

Liberty, N. Y., square 101, is in Steuben Co.

Crystal Springs, N. Y., closed.

Messages may be taken for West Farms, Westchester Co., N. Y., and delivered from Morrisania, N. Y. Charges for delivery, 25 cents.

The office at Carroll, O., square 202, printed in Tariff Book, is in Fairfield Co., and Carroll, square 211, new office in last JOURNAL, is in Ottawa Co.

Seville, O., changed to Pike Sta., O.

Adamsville, Pa., changed to Atlantic, Pa.

Goldsboro, York Co., Pa., closed.

Penobscot, Pa., P. O. A. is Mountain Top, Luzerne Co., Pa.

Pine Grove, Pike Co., Pa., changed to Mast Hope, Pa.

Penningtonville, Pa., is now W. U. office, square 59. Check direct.

[illegible] W. U. office. square 93. Check direct.

Chester Heights, closed.

Summit City, Butler Co., Pa., changed to [illegible] Pa.

Pleasant Grove, Tenn., closed.

Clarksville, Texas, printed in Tariff Book with "tariff for other lines" from Brownsville, is in Cameron Co.

Sewall's Point, Va., closed.

Menasha Junction, Wis., changed to Hilbert.

303	1 50	334.....	2 00
304.....	2 00		

On and after October first, 1873, offices in Nova Scotia and New Brunswick will check messages to or from points in Prince Edwards Island at rate of 25 and 1 for this line, and 50 and 3 for other lines.

WILLIAM ORTON,
President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Sept. 12, 1873.

On and after September 22d, Millerstown, Pa., will be added to the list of money order offices in C. O. Rowe's district.

GEO. H. MUMFORD,
Vice-President.

INFORMATION WANTED.

Information wanted as to the whereabouts of Heman S. Coats. When heard from last he was telegraphing on P. F. W. and C. Ry., under Supt. Winecoop, but he was discharged and started for Chicago. Any information will be thankfully received. His mother is greatly distressed at his continued silence.

Address letter to J. G. COATS, Union City, Randolph Co., Indiana.

BORN

CALAHAN.—At Brooklyn, N. Y., July 20, 1873, to E. A. Calahan, a daughter.

MARRIED.

BLAIRE—WAGENHALS.—At Groveport, O., Tuesday, July 15, 1873, by Rev. A. Gallagher, J. E. Blaire, of Columbus, O., to Miss Mary L. Wagenhals, of Lancaster, O.

PRATT—TUPPER.—At the residence of the bride's parents, Tuesday evening, September 2, 1873, George R. Pratt, Manager W. U. Telegraph Office, Deerfield, Ill., to Miss Lilian M. Tupper of same place.

DIED.

BROWN.—At Davenport, Iowa. August 28, 1873, Christopher H. Brown, Operator W. U. Telegraph Office, aged 20 years.

FISH.—At Oregon City, Or., August 21, 1873, Isaac P. Fish, Operator W. U. Telegraph Office, Comstock, Or., aged 21 years.

TOPPING.—At Goldsboro, N. C., in the thirtieth year of her age, Diana A., wife of Nathan B. Topping, of the W. U. Telegraph Company, formerly of 145 Broadway, New York.

TELEGRAPHERS' MUTUAL LIFE INSURANCE ASSOCIATION.

ACKNOWLEDGMENT OF RECEIPTS FOR ASSESSMENTS NOS. 44, 45, AND 46, TO SEPTEMBER 11TH.

25, 143, 148, 153, 178, 185, 187, 274, 332, 414, 695, 697, 705, 1071, 1072, 1103, 1167, 1200, 1371, 1400, 1504, 1556, 1557, 1570, 1613, 1631, 1670, 1707, 1726, 1727, 1740, 1741, 1792, 1807, 1809, 1827, 1854, 1871, 1945, 1946, 1947, 1948, 1988, 1989, 1990, 2018.

ASSESSMENT NOS. 47 AND 48.

2, 6, 16, 23, 28, 37, 52, 54, 56, 60, 64, 65, 86, 88, 91, 98, 103, 104, 106, 113. 131, 138, 140, 145, 157, 175, 188, 208, 211, 215, 217, 228, 235, 269, 277, 289, 301, 302, 311, 312, 344, 346, 349, 351, 352, 371, 380, 381, 383, 405, 413, 426, 434, 459, 463, 464, 467, 478, 509, 510, 526, 542, 547, 549, 552, 554, 564, 576, 600, 604, 646, 662, 672, 703, 711, 715, 721, 731, 740, 742, 758, 769, 787, 791, 797, 815, 821, 830, 832, 858, 859, 870, 873, 874, 876, 880, 916, 917, 923, 929, 932, 943, 1013, 1024, 1028, 1038, 1039, 1046, 1056, 1061, 1081, 1085, 1088, 1099, 1143, 1148, 1151, 1154, 1169, 1173, 1174, 1178, 1188, 1198, 1199, 1207, 1228, 1232, 1245, 1248, 1252, 1254, 1257, 1259, 1260, 1267, 1271, 1300, 1304, 1306, 1329, 1336, 1356, 1357, 1398, 1409, 1429, 1452, 1489, 1516, 1517, 1518, 1519, 1527, 1535, 1550, 1555, 1560, 1568, 1580, 1589, 1590, 1635, 1650, 1678, 1683, 1695, 1708, 1735, 1636, 1739, 1742, 1809, 1813, 1862, 1869, 1881, 1894, 1906, 1919, 1960. 1957, 1971, 2019, 2020, 2021, 2026, 2027, 2028, 2029, 2032, 2035, 2036, 2037, 2043, 2049, 2065, 2069. 2070, 2076, 2083, 2097.

The continued reception of valuable letters without a signature or number of certificate continues, and it is again necessary to caution members making remittances to be careful not only in these respects, but also to note that their letters are properly stamped before mailing, otherwise they are sent to the Dead Letter Department at Washington, and only reach their destination after a long delay, if fortunate enough to come at all.

It is incredible that among so intelligent a class of the community as is represented in our membership that so much carelessness should exist, nevertheless such is the case. Scarcely a week passes but that we are compelled to trace a letter back to its source, with no other guide than the post mark. This is often unreliable, in consequence of being illegible, and our only alternative is to pay the money over to the credit of the reserve fund.

The printed envelopes, doubtless, prevent many letters going astray. Previous to their use much carelessness was developed in addressing letters, many of which were in due time returned to the senders from Washington, whilst the bulk of them were never heard from. We are firmly convinced that thoughtlessness on the part of the sender is the cause why so many letters never reach their destination.

The annual meeting in November is expected to be of unusual importance. A new Treasurer, Secretary, and Executive Committee will be elected, and it is very desirable that the whole body of members should have a voice in the election of their officers, as well as in the other deliberations of the meeting. In consequence of the frequency of deaths during the past year (which have reached fifteen for the ten months), there is an earnest demand from two or three districts for the adoption of some plan whereby the expense of a membership with us will be lessened.

Many members are in receipt of small salaries, and cannot afford to pay the double and triple assessments which have been made so often, and they very properly demand that something should be done to relieve them of the burden. Two schemes were proposed to accomplish this object, one was to divide the membership into classes of 500 each, designate each class as A, B, and C, and to give a member the option of belonging to one class or all. The other plan was to limit payments in case of each death to $1,000, the excess paid in on any assessment to be credited to the reserve fund, which, in due time, would be drawn upon to pay a death claim, instead of assessing the members for the same. The first plan was open to the objection that it would involve too much clerical labor, and be too complicated. The second was simple, would cause no additional work in keeping the books, and it was thought that $1,000 was as great a sum as such an institutions as ours should undertake to pay at any one time. An expression of opinion of the members in general on the expediencey of adopting this latter plan was solicited. Much to the surprise of the officers it met with considerable opposition which could only be accounted for on the ground that the proposition was not thoroughly understood, and while doubtless a clear majority were in its favor, yet it thought best, in difference to the opinions of the minority to postpone the whole subject until the annual meeting. The association has grown so large, and the labor connected with keeping the books and corresponding with members has increased so greatly within the past two years, that some provision should be made for remunerating in a suitable manner, those upon whom the work, shall hereafter fall. The present officers cannot, under any circumstances serve another year on account of other duties, and it becomes a serious question to determine what arrangements shall be made for the future.

In view of these important considerations it is hoped as many as possible of the members, and especially of the agents, will be present at the annual meeting in New York on Wednesday, the 5th of November.

FOREIGN TELEGRAPHIC ITEMS

THE VICTORIA, AUSTRALIA, TELEGRAPHS.

From the returns of the telegraph department of the post-office of the colony of Victoria, Australia, it appears that there was an increase in 1872 of nearly 17 per cent. in the Victoria private messages, over the number transmitted in 1871, and an increase of 14 per cent. in the intercolonial messages.

The total number of messages transmitted over the Victoria lines in 1869, the year before the reduction of the rates, was 277,132, and the gross revenue, £34,183. The total number transmitted over the lines in 1872, the third year after the reduction of the rates, was 639,960, and the gross revenue £42,617. This large increase of business was doubtless almost entirely due to the reduction of the rates. Under the lower rates, and the consequent increase of business, the working force was necessarily augmented, which involved a large additional outlay, but it appears that this has resulted in a net gain to the department, as well as an advantage to the public. Against an estimated additional outlay, up to the end of 1872, of £7,250, there was a net increase of £8,434 in that year's receipts, and the number of messages has much more than doubled since the reduction of rates.

In 1854 the cash revenue was £223, the charge for Government messages £1,037, the number of Government messages 1,570 and the total number of messages 3,864. In 1872 the cash revenue had increased to £42,617, the charge for Government messages £7,029, the number of Government messages 85.645, and the total number of messages 639,960. A large addition was made to the business of the department towards the end of 1872, by the opening up of telegraphic communication with Europe and the East. To this the Report on the Post-Office and Telegraphic Department thus refers: "On the 21st of October, 1872, direct telegraphic communication was established by way of Port Darwin, and, with the exception of a few interruptions of short duration on the overland line, the communication has been satisfactorily maintained." After alluding to some other matters closely connected with this, the report adds: "Judging from the number of messages which have passed over the British and Australian lines up to the end of the year, the value of the Australian business may be set down at about £80,000 per annum, nearly one-half of which is contributed by Victoria." This is verified by a statement appended to the report, in which it is shown that out of the total of 1,851 messages received and transmitted for the last two months and a little better of 1872, 954, or rather more than one-half belonged to Victoria; and that out of the gross sum of £19,214 paid for these messages, Victoria contributed £9,770, or, in like manner, rather more than one-half.

THE WESTERN AND BRAZIL TELEGRAPH COMPANY.

The second section of the cables connecting Pernambuco with Bahia and Rio Janeiro will be ready for shipment on return of the steamship Hooper from the present expedition, and it is anticipated that both sections will be laid in working order before the end of the year.—*The Money Market Review*, *Aug.* 9.

THE INDO-EUROPEAN TELEGRAPH COMPANY.—Time occupied by messages in transmission from England to India, *via* Teheran:—For the week ending 22nd August, 1873: longest time taken by any message, 4 hours 10 min.; shortest time taken by any message, 17 min.; average time of all messages, 1 hour 32 min.

At the recent statutory meeting of the Eastern Extension, Australasia and China Telegraph Company, Limited, the directors' report, which was adopted, showed the gross receipts from the 1st January to the 30th June, 1873, to have amounted to £105,245; and stated that an interim dividend of 3s. per share for the quarter ending March had been paid. It was mentioned that the amalgamation had been successfully carried out without a dissent, and that, with the exception of about 1,200, the whole of the shares in the British Indian Extension Submarine and British Australian Telegraph Company, Limited, have been exchanged for new shares in the Company.

The Eastern Telegraph Company's traffic receipts for the month of July amounted to £28,975, and to £29,565 in the corresponding period of 1872.

In his Monthly Circular Mr. William Abbott says:—"The announcement that the Peruvian Government have offered to guarantee 5 per cent. upon the necessary capital for a cable to connect Peru with Panama, is most important at the present juncture, as it will no doubt lead to an early submerging of a cable that will at once become a very valuable auxiliary to the West India system.

The following is a statement showing the total number of messages forwarded from postal telegraph stations in the United Kingdom during the week ended the 23rd of August, 1873, and during the corresponding week of 1872:—Week ended August 23, 1873, 365,484 messages; week ended August 24, 1872, 329,201; increase in the week of 1873 on that of 1872, 36,283.

The telegraph cable which was laid between Kingston and Aspinwall, and twice lost, has again been recovered.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, SEPTEMBER 15, 1873.

MINISTER SCHENCK AGAIN.

It does appear as though that "American gentleman residing in Paris" had changed his domicile to London. Some one of about the calibre of that famous person evidently has been playing upon Minister Schenck's finer feelings—his well-known hatred of corruption—and so aroused that irascible diplomat that he has been provoked into an onslaught upon the Atlantic Cable and the Western Union Companies, which has resulted in his grievous discomfiture. His ignorance concerning the charges which he brought against the companies, and the animus by which he was actuated, was so thoroughly exposed by President Orton that but few expected a rejoinder. However, one came, bearing evidence of a mind greatly disturbed, reiterating a portion of his former charges, for the correctness of which he now calls upon Mr. Orton to furnish proof.

The closing portion of the letter is interesting only so far as to show what a man will say when he loses his case and his temper.

Who is using this unfortunate gentleman to draw chestnuts out of the fire?

THE DUPLEX [illegible] SUCCESSFULLY APPLIED TO SUBMARINE [illegible]

The applicability of the Duplex system to ocean cable service, has been successfully demonstrated by the Eastern Telegraph Company, who are now working it upon the sections of their cables between Lisbon and Gibraltar, (330 miles), and Malta and Alexandria, (950 miles).

As soon as the necessary instruments can be obtained, the electricians, profiting by the experience they have acquired on the shorter cables, fully expect to be able to apply the system also successfully to the longer sections between Malta and Gibraltar, (1120 miles), between Suez and Aden, (1450 miles), and between Aden and Bombay, (1820 miles). It is impossible to overrate the importance of these improvements, for, when perfected, they practically at once double the carrying capacity of all existing submarine cables, a fact which must have considerable influence upon their value as paying investments.

AIMLESS EDUCATION.

In a recent issue, in commenting upon the aimless character of the education of our youth at the public schools, we took occasion to place before our readers and those who controlled the course of studies pursued at the educational institutions, the propriety of teaching some useful business pursuit which would prove beneficial to the scholar in after life, and instanced chiefly, the business of the telegraph. Since that article appeared, a number of newspapers in different sections of the country have taken up the subject, and, in a general manner, while not recommending any particular course, point out the necessity of giving aim to education. The commencement of the scholastic year is an appropriate time to urge upon those in authority the necessity of consideration and of action.

What is needed in our public and private schools, is not so much a cramming of the student with knowledge utterly useless to him in fighting the battle of life, as to furnish weapons calculated to render him independent and contented. Notwithstanding the fact, that teachers as a class, resist the idea of fitting the scholar for life duty, as the proper end of their vocation, nothing is more true than that this should be the end aimed at. Such a reform is urgently needed, and in carrying it out, our school boards and teachers will realize that their work will result in the permanent welfare of those committed to their care, in a much greater degree than is possible from the course now pursued.

The telegraph service is in need of many operators of this intelligent class, and the necessity grows stronger daily with the expansion of the lines. Good telegraph operators are a public necessity, and in supplying them, the school managers would directly benefit the public, the scholar, and the telegraph companies.

In adopting this and kindred expedients for keeping to the prime end—education as a fitting for life work,—we are confident that the various burdens of society would be greatly reduced, crime and pauperism be checked, and the people saved a large portion of the money they are now forced to waste on the [illegible] and the vicious—in many cases made so from discontent, or a [illegible] opportunity to earn an honest livelihood in the sphere to which [illegible] have been educated.

THE INDUSTRIAL EXPOSITION AT CINCINNATI.—The fourth Industrial Exposition opened at Cincinnati, on Wednesday, 3d instant. These Expositions are far more successful and satisfactory than any which have taken place in the United States, and this one more interesting than any preceding. No less than twenty-three premiums for electrical and telegraph apparatus are offered, and the display in this line is unusally fine. The Exposition will continue open until Saturday, October 4th.

Mr. George H. Grace has been appointed General Superintendent of the Southern and Atlantic Telegraph Company's lines, with head-quarters at Macon, Ga.

THEN AND NOW.

We read a few days ago, in a reprint of the original *Maryland Journal and Baltimore Advertiser*, an account of the difficulties encountered in establishing a weekly newspaper in Baltimore, the first copy of which was issued just one hundred years ago last month. The employment of a "post rider" between Baltimore and Philadelphia, was referred to as one of the serious items of expense. He was to set out from Philadelphia early Monday morning, and was expected to reach Baltimore Tuesday evening, and to bring the "freshest advices," (from one to four weeks old), from New York and Boston, and sometimes to bring information from Europe, which occasionally arrived in the royal mails. While reading this quaintly expressed editorial article a century old, a memorandum was handed to us, the substance of which we give below, and which strikingly illustrates the difference between then and now:

Not long since, a gentleman called at the Western Union Telegraph Company's principal office in New York, to forward a message to St. John, N B., eight hundred miles distant. The message was forwarded to St. John, and the answer procured and delivered to the sender of the first message in New York, in twenty-two minutes.

A lady called at the same office a few mornings ago, to forward a message to Bradford, an interior town in England, remarking that she would wait for the answer; and in three hours and thirty five minutes, the desired reply was safely delivered to her.

While it is not customary for correspondents to wait in our offices for replies from Europe, it frequently happens that they are returned within an hour, and sometimes in forty minutes.

Verily this is an age of progress.

THE LISBON AND RIO JANEIRO CABLE.

The work of laying a cable between Portugal and Brazil, was commenced on the 21st ultimo. On the 26th, after paying out over 400 miles of cable, the expedition was stopped by the discovery of a fault in the wire. From tests which were made, it is believed that the fault is near the land. It was decided to continue paying out the cable until Madeira was reached, whence the cable steamer will probably have to return to repair the fault.

Later advices state that the cable is broken at a point 180 miles from Madeira.

RETURN OF MR. W. H. ABEL.

Mr. W. H. Abel, for many years Auditor of the Western Union Telegraph Company, who went abroad last Autumn for his health, arrived here by the Steamer Nevada, on the 2d instant, and was warmly welcomed at the Quarantine by a large concourse of his friends, who went down the Bay in a steamer, especially engaged for this purpose, and brought him to the city. Mr. Abel spent the Winter in the south of France and Italy, and the Summer in Switzerland, and has returned considerably improved in voice and general health, but is not sufficiently restored to warrant his return to active business at present.

Mr. Abel desires, through the JOURNAL, to grasp the hands of his old friends and associates, and to express his great pleasure at being once more in their midst.

THE NEW OFFICE OF THE WESTERN UNION TELEGRAPH CO. IN OMAHA.

The Western Union Telegraph Company recently opened a new office at Omaha, in the Grand Central Hotel. The office, with all its appointments, is without doubt the handsomest and most complete for its size of any in this country. For the following particulars we are indebted to the *Bee*. Upon entering the door, one is confronted by an elegant counter, surmounted by a ground glass partition, in which are a couple of apertures and writing desks at which the business with the office is transacted. At the left are the manager's desk and safe, upon a platform, surrounded by a railing. Behind the counter are five beautifully finished tables, made of ash, with black walnut mouldings. The first table is fitted up for seven instruments, one pair of button repeaters, and one set of the latest automatic repeaters, called the "Milliken-Hicks." Each of the other four tables are supplied with four instruments each, making in all twenty-three instruments. Each table is divided into four compartments by glass partitions, and furnished with an Argand gas burner, which comes up through the centre. The switch board is of the very latest manufacture, and is from the shop of Mr. Henning, of Ottawa, Illinois. It is fitted for thirty-two wires, and is composed of 2,000 pieces of brass. Fourteen wires are now worked out of this office. The batteries are in the basement, and consist of sixty cups of Grove main battery, and forty cups of Gravity local battery.

The office is perfect in all its details, nothing having been forgotten to make it second to none. It presents a handsome and comfortable appearance, and the gentlemen connected with the office have good reason to feel proud of their new quarters. The superintendent of the Western division is Mr. W. B. Hibbard, whose headquarters are now at Salt Lake. Mr. Frank Lehmer is the manager of the Omaha office, and Mr. William Lehmer cashier. There are five day and three night operators, Mr. F. B. Knight being the chief operator.

THE SURVEY FOR A SUBMARINE CABLE BETWEEN THE UNITED STATES AND JAPAN.

Commander George E. Belknap, commanding the United States steamer Tuscarora, reports to the Navy Department, under date of August 30, that he expected to proceed to sea from San Francisco on September 2, on the special service of surveying a route for a submarine cable from the west coast of the United States to China and Japan. The survey will commence from some point in the vicinity of Puget Sound. From that place the Tuscarora will proceed to the Aleutian Islands, and it is expected she will reach the island of Atcha. It is not probable that much progress will be made in the survey this season, as the weather will soon be unfavorable for it. In that case the vessel will be employed until Spring in getting the continental outline between San Francisco and the end of the California Peninsula, sounding off and on shore until she ascertains the true ocean bed. An experience will thus be obtained which will enable her to execute her orders with more certainty. An official report from Commander Belknap states that he has a new sounding apparatus, made on the plan of Sir William Thompson's, and he has no doubt of the success of the survey. At Puget's Sound he will first ascertain the most favorable spot to land the cable, his efforts being to secure one where the water is deepest and where vessels do not anchor.

OBITUARY.

SIR FRANCIS RONALDS, F. R. S.

The English journals record the occurrence of the death of Sir Francis Ronalds, F. R. S., the eminent scientist, at his residence, St Mary's Villa, Battle, Sussex. He expired in the eighty-sixth year of his age.

Born in the year 1787 or early in 1788, the son of a plain gentlemen, at Highbury, and brought up at a school in Hertfordshire, where both mathematics and the physical sciences were taught, he began early to devote himself to the theoretic study of those subjects in the practical application of which, at a subsequent date, he rose to such eminence. It was as nearly as possible sixty years ago—namely, in 1813 or 1814—that having made the acquaintance of M. De Luc, a French savant, then engaged in a series of electrical experiments, he became so interested in the subject that he resolved to turn his attention to electricity as the serious business of life. The researches which he made with the view of ascertaining the degrees of quantity and electricity in the electric pile and his invention of a clock to be kept in motion by electro-galvanic power were described severel years ago in the pages of the *Philosophical Magazine*. Mr. Ronalds also, it is said, was bold enough, in 1816, to propose the laying down of one of his electric telegraphs between St. James' Palace and Brighton, which at that time was the usual residence of the Prince Regent, but was snubbed by a red tape reply from Lord Melville and his brother Lords of the Admiralty, to the effect that the telegraph already in use—viz., the clumsy wooden apparatus that till lately surmounted that department in Whitehall—was quite sufficient for any existing requirements, and that no new one was wanted. And so the electric telegraph was "shelved" for a time, being destined to lie dormant until again it should be woke up into action, or the nation woke up to appreciate it, by the conjoined labors of Cooke and Wheatstone. It should, in justice to Sir Francis Ronalds, be mentioned here that a pamphlet which he gave to the world as far back as the year 1823 contained full accounts not only of his electric telegraph, but of an improved electric machine, of a new mode of electric insulation, of an electrograph for recording electro changes, and a pendulum doubler for the induction of a continued flow of electricity, together with his attempt to apply M. De Luc's column to the measurement of time, and his experimental observations on Mount Vesuvius and in Sicily. In 1825 he invented a perspective tracing instrument to facilitate drawing from nature or from plains and elevations. This machine was employed by him and Dr. Blair ten years afterwards, in order to procure exact perspective projections of the Celtic remains in Brittany. In 1843 he was appointed the first (honorary) director of the observatory at Kew Gardens, and the duties of this post he discharged with great zeal and energy down to 1852, when he retired, obtaining at the same time a well-merited pension on the Civil List. Several years before this he had been elected a fellow of the Royal Society, in acknowledgement of his applications of electrical science; but it was not until 1870 that the man whose labors in telegraphic investigation, as stated in his patent, had been alike "early" and "remarkable," received that small honor of knighthood. It only remains to add that to his ingenuity are due several great improvements in instruments and methods of testing and recording the natural phenomena, the atmospheric electric conductor, the photo-barograph, the photo-thermograph, the photo-electrograph, and the photo-magnetograph—all varied applications of one and the same discovery. He described all these various instruments in the reports and transactions of different learned societies, and we believe that his atmospheric electro conductor has been adopted in the observatories of Greenwich, Madrid and Bombay, while his photo-baragraph and photo-thermograph are in use at the Radcliffe Observatory at Oxford. In 1845 he received a government reward for his invention of photographic self-registering meteorological and magnetical instruments.

A FISH STORY—NEW DIFFICULTY FOR SUBMARINE TELEGRAPHS.

A correspondent of the London *Times*, in a communication published in that paper of the 12th ulto., narrates the following incident, which developes a new and hitherto unexpected danger to submarine telegraph cables. The communication is dated Kurrachee, July 8, and is signed H. Izaak Walton:

"As the following incident relating to submarine telegraphy may interest a large portion of your readers, I send you the account, in the hope that you may think it worthy of publication in *The Times*.

"The cable between Kurrachee and Gwadur (a distance of about three hundred miles) suddenly failed on the evening of the 4th instant. The telegraph steamer Amber Witch, under command of Captain Bishop (late I. N.), with the electrical and engineering staff under Mr. Henry Mance, proceeded on the following day to repair the damage, which by tests taken at either end appeared to be one hundred and eighteen miles from Kurrachee. The Amber Witch arrived on the ground at 2 P. M. on the 6th, a heavy sea and thick fog prevailing at the time, but the cable was successfully grappled within a quarter of a mile of the fault.

"The soundings at the fault were very irregular, with over-falls from thirty to seventy fathoms. On winding in the cable unusual resistance was experienced, as if it were foul of rocks, but after persevering for some time the body of an immense whale, entangled in the cable, was brought to the surface, when it was found to be firmly secured by two and a half turns of the cable immediately above the tail. Sharks and other fish had partially eaten the body, which was rapidly decomposing, the jaws falling away on reaching the surface. The tail, which measured fully twelve feet across, was perfect, and covered with barnacles at the extremities. The sea being too rough at the time to make use of the boats, an attempt was made to haul the whale on board, but its own weight broke it away from the injured cable as soon as it was raised above the surface.

"Apparently the whale was, at the time of entanglement, using the cable to free itself from parasites, such as barnacles, which annoy them very much, and the cable, hanging in a loop over a submarine precipice, he probably, with a fillip of his tail, twisted it round him, and thus come to an untimely end.

"During the time the Amber Witch remained on the ground a large school of whales continued to play in the close vicinity of the ship, frequently blowing within a dozen yards of the vessel, and even rubbing themselves against the hawser by which the ship was secured.

"As the officers were engaged in repairing the late fault, and the boatmen who accompanied me in 1862 are all accessible, I must refer any skeptical readers to them for corroboration of my statement."

Mr. JOSEPH ANGELL, late chief operator in the Erie Railway office in New York, has been appointed Superintendent of Telegraph on the New York & Oswego Midland Railroad.

A REMINISCENCE.

One evening, not in eighteen hundred and blank, but plain 1855, the subscriber, then an adolescent plug of some fifteen Summers, arrived at the village of E——, away down South, to assume the position of assistant operator in the telegraph office there. The last lingering rays of the sun were not gilding the western horizon half as effectually as they were performing that operation for the end of my nose. Within a few hours after my arrival, I had reported for duty to the manager, Col. G——, who was also a lawyer and politician of note, and was duly installed. So far as I know, no "unabridged" has ever defined the meaning of "assistant" or "cub." It appeared in those days to be one of the most comprehensive terms in the language. It included the duties of operator, clerk, book-keeper, receiver, manager, messenger, battery-man, line repairer, janitor, and all others connected directly or indirectly with an office like E——. Having shown me into the office and battery-room, the Colonel promptly washed his hands of the whole concern, and went off to attend to his law practice and political affairs, leaving me entirely to my own reflections and devices, which were various. They included sundry original methods of performing the duties of the office, some of which I have never seen practised since. The Colonel's salary was forty dollars per month, whereof he bestowed twenty on me, and made the other twenty clear of expense and trouble. As board and washing cost but $9.25 per month at E——, I had a pretty large proportionate margin left for other expenses and profit.

The office at E—— presented a far more useful than ornamental appearance. In surveying the solitary, unpainted operating table; the old-fashioned dirty instruments, with an avalanche of ribbon paper tumbling into a huge box; the straggling, uninsulated office wires; the battery-room, with tables and floors disintegrated by acids; the cobwebs and dust that liberally bespread everything in sight: no one would have acquired the smallest idea of the neat and trim W. U. office of these latter days. Nevertheless, I felt very happy and independent in my new premises. There was but one misgiving in my mind. I felt that I could "run" the office pretty well; but there remained the question of repairing, with the disquieting adjunct of climbing. Of this latter, I was compelled to confess to myself entire ignorance and a general horror. I remembered watching one day,—several years before my advent into telegraphy,—an awkward chap trying to make his way up a pole. This genius adopted the plan of putting out both his climber points at once, making at the same time a grab at the blue heavens above, with the legitimate result. As I had no reason to doubt that he was a properly educated repairer, I had nearly reached the conclusion that the whole climbing system was a "fraud." In this state of mind, for the first few days after my arrival at E——, I watched every threatening cloud with secret apprehension, for I knew that almost every storm laid trees across the wires in the heavily timbered country through which they ran. But relief was near. Before the clouds had made up their minds to go into that sort of criminal proceeding, Jabe J—— called and introduced himself. Jabe had been my predecessor as cub, but, after some months' trial, the mysteries of Morse had proved too deep for him, and he had abandoned them for the less complicated business of clerking in a country store. He was about my own age, sandy-haired, and had a bold countenance, in which freckles and tobacco juice had a considerable struggle. He wore no coat, and but one suspender,—which, however, was of a bright copperas color,—and was possessed altogether of a striking air of independence and assurance. His true name was probably Jabez, but Jabe was what he was called. A few hours made us quite intimate. He confidentially informed me of his dislike of the key, and I admitted my ignorance and apprehensions of the climbers. But together we made up a sort of compensation-balance system. He claimed to be "nearly lightning" on climbing, whilst I treated of reading by sound as a trivial matter. So we made a mutual compact—I to teach him to operate, he to initiate me into the art of getting up and down big trees without damaging myself. I say trees, because there were no poles except through the streets of towns, and farms and "clearings" in the country. We were shortly afforded an opportunity of putting Jabe's part of the agreement into practical operation. A thunder-storm swept over the line one night, and the only fluid I could taste from towards P—— next morning was in the shape of a parting shock of lightning, which came very near knocking me off the tall three-legged office stool. After postponing the inevitable as long as possible, I summoned Jabe, and gathering up the tools, wire, and other repairing paraphernalia, we started "out on the line." About 15 miles jaunt through the wilderness brought us to the scene of disaster. A tree had fallen across the line, and the broken wire had slipped out of an insulator, fastened some twenty-five feet up a large oak. After considerable difficulty and perspiration, we got the wire drawn together and spliced, and it remained only to replace it in the glass. Jabe became taciturn. After a long rest, he buckled on the climbers, with an air of solemnity befitting so important a matter, and a deliberation that set the sun several feet further westward. Finally there was no longer a strap, or a buckle-tongue remaining unadjusted, nor any other sufficient reason why the climbing should not begin, and after fastening an end of the pulley rope to the strap of his trowsers behind, Jabe began it. So far from the violent gymnastics of the other man I had seen climbing, Jabe went slowly, up, trying each place he thrust the climber-points into, two or three times, with violent kicks and a corresponding number of grunts; his legs far apart, and his long rope tail uncoiling slowly behind him. About 15 feet up, he remarked between grunts: "These cussed climbers never did fit me nohow." I replied to the effect that there did seem to be something wrong about them. This was all the conversation that took place while he was going up. Arriving at the bracket, he seemed to have made up his mind not to stop there. It was probably not a very interesting place. Anyway Jabe crept on, until he reached a large limb above the bracket, astride of which he seated himself, and proceeded to puff and blow, and to hold on very tightly. I said to myself, "this is skill, it is science; he went up that extra distance, just to show me he wasn't afraid to climb even higher than necessary. Jabe is a first-class repairer; but the work looks so hard that I believe I'll resign. Afterwhile Jabe recovered his breath sufficiently to pull the wire up, by the pulley rope, which I had made fast to it below, and a little awkwardly I thought, succeeded in droping it into the glass below him. As the line was O K now, and it was getting late in the day, I busied myself with collecting the tools and preparing for our start homeward. Some time elapsed before I had everything ready, when, looking up, to my surprise I beheld Jabe still ensconsed on the limb. I at once urged him to come down, as we had no time to spare. He said, "These durned climbers never were any account." This seemed aside from the main point, and I simply repeated my previous observations. Then Jabe said: "This tree has got the meanest bark I ever saw." I made no attempt to combat this proposition, seeing that the tree did have a rough exterior, but contented myself with warning him that we would be in the night getting home, if he didn't come down at once. Perceiving the correctness of my view upon this matter, he put one of his feet down a few inches, and gave a feeble kick, which failed to strike his climber well into the tree, and it consequently slipped out, the moment his weight partially rested on it; whereupon he hastly scrambled back to the limb, and observed with a degree of feeling, that he wished I would go up to old Mr. Jones—some five miles off—and borrow a ladder to get him down with. For the first time I had a misgiving of Jake. I told him it would take until late at night to do that, even if Jones had a ladder, which was improbable; and hazarded the opinion that as he had gone *up* the tree, he could certainly come *down* it. Upon this he informed me, that coming down was a "dog goned sight" harder than going up; and that he wouldn't come down until I got a ladder for him. We were both getting a little excited, and I wound up the discussion by notifying him, that if he didn't come down at once, I would drive off, and leave him to stay up there all night, and as much longer as might suit his convenience. At this Jabe began to cry, and call names; and when I actually drove off a few yards to stir him up, he increased the cry to a howl, and started down the tree. His start was slow and painfully laborious, but after descending a short distance, he must have changed his mind, for he suddenly seemed to let go all hold and came down "by the run." Bark, skin, and clothing flew, and when he raised himself up from the foot of the tree and started towards me, he presented a curious aspect, and was mad about something. "In the scene that ensued," I *did* take a hand, but might as well draw a veil over it. The compact was broken.

J. S. B.

PRIZES FOR ELECTRICAL SUBJECTS OFFERED BY THE SOCIETY OF ARTS.—Among the general prizes of gold and silver medals offered by the Society of Arts are the following:—

A Galvanic Element which shall combine the constancy of the Daniell's cell with the low resistance and high electromotive force of a Grove's cell.

An Electric Condenser which shall combine high capacity with small bulk, and small residual charge.

A Sensative Pocket Galvanometer.—The size should not exceed that of a watch.

To which may be added, as of use in telegraphy,—

A Varnish or coating which can be applied to iron wires so as to protect them against rust, and which shall not be liable to chip off when the wire is bent or rubbed.

Electric Weaving.—To the manufacturer who first practically applies electricity to the production commercially of figured fabrics in the loom.

Telegraphs.—For an economic and permanent means of telegraphing through uninsulated wires, between places not less than 1000 miles apart.

Patented inventions are not excluded from receiving the Society's rewards. The Council reserve to themselves the right of withholding all or any of the above medals or premiums, as the judges may report. The Council is willing to receive communications on subjects not included in the above list, The degree of originality and value of suggested improvements will have material influence on the adjudication of the award. In all cases a full account and description of the invention for which a medal or premium is sought must be sent to the Society. All communi-

Digitized by Google

cations must be written on foolscap paper, on one side only, with an inch and a quarter margin: they must be accompanied by such drawings, models, or specimens, as may be necessary to illustrate the subject. The drawings should be on a sufficiently large scale to be seen from a distance when suspended on the walls of a meeting-room. All communications and articles intended for competition must be delivered, addressed to the Secretary, at the Society's House, free of expense either on or before the 31st December, 1873 or 1874, except where otherwise stated. In the first case they will be considered during the Session 1873-4; in the second case during the Session 1874-5. Any communication rewarded by the Society, or any paper read at an ordinary meeting, will be considered as the property of the Society. Should the Council delay its publication beyond twelve months after the date of its being rewarded or read, the author will be permitted to take a copy of the same, and to publish it in any way he thinks fit.

RESISTANCE OF WIRES.

(*From the Telegraphic Journal.*)

By JAMES GRAVES.

In a foot-note on page 22 of No 11 of the TELEGRAPHIC JOURNAL, it is stated that "it is open to future investigation to determine whether a body which offers a unit of resistance to one cell, offers neither more nor less than a unit of resistance to a hundred cells."

Since reading this I have accurately adjusted two separate ohms of No. 20 German silver wire, and used them as a Wheatstone's bridge.

As a first experiment I put on the third side of the parallelogram a resistance of four-hundredths of a Varley unit (0·04 V. U.), and on the remaining side 1·1 ohm by Varley. These exactly balanced each other with 1 cell, 50 cells, and then 1 cell again, not a shadow of difference being observed on the galvanometer, which was a very delicate astatic mirror, whose resistance was 5854 ohms.

Secondly, I increase the resistance on the third side to 0·81 V. U which exactly balanced 20·6 ohms, and this arrangement gave the same result with 1 as with 50 cells.

As the resistance of the galvanometer, being very high in comparison with the four branches of the parallelogram, might account for this result, I prepared a mirror galvanometer, bound with 4 yards of No. 16 copper wire, having a resistance of about six-hundredths (0.06) of an ohm.

With the same bridge of equal ohms, I took a length of 30 inches of No. 18 copper wire for the third and fourth sides, and following the bridge round I found a spot at which the balance was perfect; the addition of one-tenth of an inch either side of this spot gave a perceptible deflection. I then measured the length of the two halves, and found them exactly 15 inches each between the points of contact. With 1 cell or with 15 cells the result was precisely the same. Two sides of this parallelogram were of German silver and two of copper; they would therefore be equally affected thermally.

In another experiment I used the same bridge and galvanometer. On the third side I placed ¼ an ohm of German silver, and on the fourth side a length of No. 24 copper wire, sufficient to make a perfect balance with momentary battery contacts. This gave the same result with 1 as with 50 cells, alternated three times with an interval between.

With this same arrangement, 1 cell in permanent contact three minutes showed no alteration; 50 cells on three minutes gave evidence of slight motion, which, by making and breaking, could be increased to an oscillation in the direction of an increase in the copper side, showing the unequal effects of heating. Practically, as far as these experiments show, a standard unit of resistence remains the same for low as well as for high power.

Valentia, December 19, 1872.

Repairers' Tools constantly on hand.,

Importers and Dealers in best English and American Galvanized Wire.

MANIFOLD PAPER, for Train Orders, etc. Also, AGATE PENS.

In fact, everything used in connection with TELEGRAPH LINES we are prepared to furnish, and equip any length of line in the shortest possible time. Having our own Foundry, we can furnish Brass Castings of any description at moderate price

L. G. TILLOTSON & CO.

No. 8 DEY STREET, NEW YORK,

MANUFACTURERS, IMPORTERS,

AND

DEALERS IN EVERY DESCRIPTION

OF

TELEGRAPHIC

AND

Electrical Apparatus.

Sole Agents for RICH'D JOHNSON & NEPHEW'S celebrated Line Wire.

" " BISHOP GUTTA PERCHA CO.'S Cables and Insulated Wires.

" " CAUVET Pat. Screw Insulators.

" " AMERICAN COMPOUND WIRE COMPANY.

" " BROOK'S Patent Paraffin Insulators.

" " HILL'S Patent Galvanic Battery.

" " LECLANCHE Patent French Battery.

MANUFACTURERS OF

Premium Registers, Relays, Keys, Pocket Magnets, Sounders, Switch Boards, Circuit Closers, Cut-Outs, Lightning Arresters, Paper Reels, Carbon Battery, Daniell's Battery, Grove Battery,

IMPORTERS OF

QUICKSILVER, PLATINUM, ETC.

ENTIRE EQUIPMENT FOR TELEGRAPH LINES

Of any Length, always on Hand.

Sole Proprietors and Publishers of

SMITH'S MANUAL OF TELEGRAPHY,

REPAIRING TOOLS, STATIONERY, ETC.

Putt's Mechanical Telegraph Instrument.

THE LECLANCHE BATTERY.

This Battery (the invention of GEORGE B. LECLANCHE of Paris) possesses great advantages over any other now in use, in its *great endurance*, its *cleanliness*, its *economy* and its *simplicity*.

We have now perfected arrangements by which we shall at all time be able to supply the rapidly increasing demand in this country.

PRICES:

No. 1, per cell,	*$2.25*
" 2, "	*1.80*
" 3, "	*1.75*

F. L. POPE & CO.

Manufacturers and Dealers in

Telegraph Instruments and Supplies

OF EVERY DESCRIPTION,

38 Vesey Street, New York.

New and Superior patterns of

STANDARD TELEGRAPH INSTRUMENTS.

Their RELAYS, SOUNDERS, and KEYS which have been specially designed by Mr. F. L. Pope, are elegantly designed, thoroughly well finished and scientifically adapted to the service required and are recommended as SUPERIOR TO ANY HITHERTO OFFERED.

In addition to these ALL DESCRIPTIONS OF TELEGRAPH MATERIALS AND SUPPLIES are furnished, such as

INSULATORS, BATTERIES,
INSULATED WIRES,
CHEMICALS., ETC, ETC.

MAGNETIC AND DIAL INSTRUMENTS.

We have for sale also THE NONPAREIL TELEGRAPH INSTRUMENT for amateurs, learners and short lines.

A COMBINATION SET, comprising Sounder and Key on a handsome rosewood base.

Bradley's Box Relays and Sounders.

Bradley's Apparatus for Electrical Measurement.

Bradley's Naked Wire Helices and Magnet Spools to order, any desired size and resistance, at manufacturers' lowest price.

Descriptive Circular and Price Lists forwarded upon application to

F. L. POPE & CO.,

P. O. Box 6010 *38 Vesey St., N. Y.*

THE LECLANCHE BATTERY CO.

Offer for Sale this celebrated Battery,

(SECURED BY LETTERS PATENT,)

Of which they are the exclusive owners in this country.

Over 300,000 are now in use in Europe,

and have recently been adopted by the French Government in preference to the Calland, which had been used by them for several years.

WE RECOMMEND THEM FOR

Telegraphy (open circuit), Railroad Signals, Hotel Annunciators, Burglar Alarms, Electric Bells, Clocks, &c.

AMONG ITS NUMEROUS ADVANTAGES ARE—

ABSENCE OF ACIDS AND SALTS OF COPPER,

ITS GREAT CLEANLINESS,

WONDERFUL DURABILITY,

ECONOMY IN RUNNING EXPENSES,

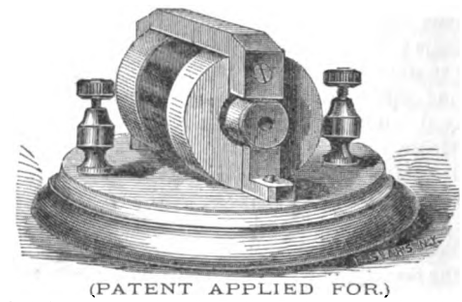
ENTIRE ABSENCE OF ODOR.

This Battery will last without any attention from six months to three years.

A large number of Cups are already in use in this country on Burglar Alarms, Electric Bells, &c., and are giving entire satisfaction. The Western Union has a number of Cups put up November 26th, 1872, that are still running.

For further particulars apply to

THE LECLANCHE BATTERY CO.,



No. 40 West Eighteenth Street.

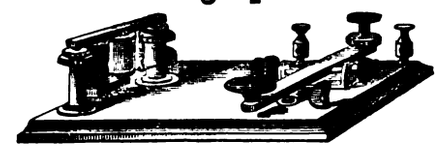
No. 8 Dey Street, New York.

SOMETHING NEW.

"The Rattler" Telegraph Sounder.

(PATENT APPLIED FOR.)

This is a very simple and effective Instrument, and, as it does not require any spring to draw the lever back, is always adjusted.



PRICE, - - - - $3.50.

L. G. TILLOTSON & CO.,

No. 8 DEY STREET, N. Y.

TILLOTSON'S EXCELSIOR

Telegraph Instrument.

(PATENT APPLIED FOR.)

This apparatus is constructed of the best material, and finished equal to any Telegraph Instrument, and is warranted first class in every particular. It is especially adapted to the requirements of Students of Telegraphy and the operation of Private Telegraph Lines.

Price, complete, Sounder and Key mounted on finely finished, Mahogany Base, with one Cell Hill's Patent Battery, with Chemicals, eight feet of Office Wire, and "Smith's Manual of Telegraphy"	$7 50
Two sets	14 50
Price of Sounder and Key only	6 50
" " " with Cut Out and Lightning Arrester attached	7 50

SEND FOR CIRCULAR.

L. G. TILLOTSON & CO.

No. 8 DEY STREET, N. Y.

TILLOTSON'S NICKEL PLATED

POCKET RELAYS,

IN HARD RUBBER CASES.

A most convenient and useful Instrument for Telegraphers—equally available for the office or the field. Will work readily on an ordinary circuit of 300 miles, and only occupies a space of 5 x 2 inches.

Illustrated on page 56 of our Price List.

L. G. TILLOTSON & CO.,

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 21. NEW YORK, OCTOBER 1, 1873. WHOLE NO. 142.

MEASUREMENT OF ELECTRO-MOTIVE FORCES.

Until some recognized standard of electro-motive force is adopted, this measure can only be given in terms of the force of some other battery. Its measurement may be obtained on two systems—either by the application of Ohm's law to a battery in action, where the resistances are known, or by allowing the battery to remain inactive, and measuring the tension, in which cases the tension is the same as the electro-motive force, and the resistances in circuit need not be known. The first five of the following methods belong to the former system, and Poggendorff's method is a combination of both.

To compare the electro-motive forces of two batteries:

1. Let their force be E and E'; join them up successively in circuit with the same galvanometer, and, by varying their resistance, cause them both to give the same deflection; their forces will then be in direct proportion to the total resistances in circuit in each case, or

$$E' = E \times \frac{R'}{R}$$

where R represents the resistance with E (including that of battery, galvanometer, and the variable resistance), and R' with E'.

2. If the external resistances be made very large indeed in comparison with that of the cells themselves, their internal resistance may often in practice be neglected, and only those of the galvanometer and resistance coil taken into account.

3. Where the electro-motive forces differ greatly it is often necessary to employ a shunt to diminish the deflection of the galvanometer and bring it within range with the more powerful battery. Calling their resistances g and s, their point of resistance will be

$$\frac{g \times s}{g + s}$$

which must be employed in calculating the total resistance of R; the respective electro-motive forces are then

$$E' = E \times \frac{R \times \frac{g+s}{s}}{R' + g}$$

4. Where shunts are used in obtaining both the deflections, the formula becomes

$$E' = E \times \frac{R \times \frac{g+s}{s}}{R' \times \frac{g+s'}{s'}}$$

In all these cases $\frac{g+s}{s}$ represents the multiplying power of the shunt.

5. When a Thomson's reflecting galvanometer is employed (or any other in which the deflections have a known value), it becomes unnecessary to reproduce the same deflection. Calling the deflections d and d', we have:

$$E' = E \times \frac{R \times d}{R' \times d'}$$

6. *By the direct opposition of cells.*—Where a number of cells are joined up in a circuit with, but in opposition to, a number of other cells with a galvanometer inserted, and the numbers adjusted so that no current passes, we have an obvious measure of their electro-motive force.

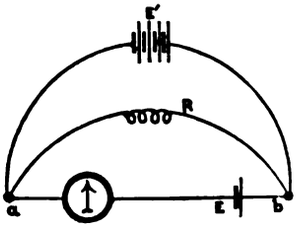

Figure 1.

7. *By Poggendorff's method.*—In this method (Fig. 1) the more powerful battery, E', is joined up in circuit with a resistance coil R, and the other battery E and a galvanometer are connected to the same coil, so that both batteries send a current through R in the same direction; by increasing the resistance of R it is easy either to make the current of E' overpower that of E, or to obtain such an equilibrium that E' shall remain inactive, and no current pass through the galvanometer in either direction. When this is effected we have the following ratio: as the total resistance of E' and R is to the resistance of R so is the electro-motive force of E, or

$$E = E' \times \frac{R}{E' + R}$$

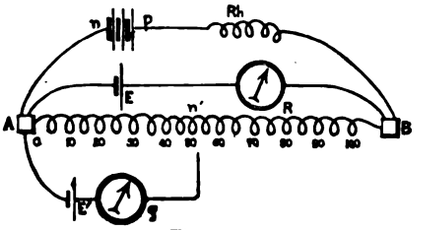

Figure 2.

8. *By Clark's Potentiometer.*—It has been objected to the preceding system, that since one of the batteries is active and the other not we do not obtain a true comparison of the forces. Although attaching little importance to this objection, the author has for many years past employed an instrument depending on similar principles to which this consideration does not apply.

R is a coil of platinum wire of 100 turns, wound on an ebonite cylinder, which revolves on its axis like a Wheatone's rheostat; the ends of the coil are connected to the axles, which work in the blocks A and B; $p\ n$ is a battery of several cells, also connected to the blocks A and B, which sends a continuous current through R. A rheostat, Rh, is also inserted, by which the total resistance of the circuit can be varied. E is a standard element (or a thermo-electric pile), also connected to the blocks A and B with an intervening galvanometer, which, by a proper adjustment of the rheostat, is just balanced by the battery $p\ n$ in the manner before described, so that no current passes. Thus far the arrangement is similar to that of Poggendorff, except that E is used as the standard of comparison instead of $p\ n$. E' is the cell whose tension or electro-motive force we desire to measure, and this is connected with the block A and galvanometer g, and a moveable wire n which can be applied to any part of the wire R.

Assuming the standard battery E to be exactly balanced by $p\ n$ and to have a tension of 100, and calling the tension at $A = 0$, we have between A and B every tension from 0 to 100; and by applying the wire n successively to different parts of the wire R we soon find a point where the tension of E is balanced, no current passing through g. A scale of equal parts measured along R gives the tension of the cell E' by simple inspection.

By the use of a Thomson's galvanometer, and by fixing a divided scale on the revolving cylinder, it is easy to measure tensions accurately to the ten-thousandth or hundred-thousandth part of a Daniell's cell. When the battery E' which we wish to measure is more powerful than the standard battery E, their positions are reversed and E is connected to the galvanometer g and wire n. When this is the case, employing a scale of 100 parts and calling n the number of divisions, we have

$$E = E \times \frac{100}{n}$$

Table giving approximately the electro-motive force of different batteries.

Grove's	100
Bunsen's	98
Leclanché	75
Daniell's	56
Smee's (not in action)	57
Smee's (in action) about	25
Copper and zinc in acid (Woolaston's)	46
Sulphate mercury and graphite (Marie Davy)	76
Chloride silver	62
Chloride lead	30

The foregoing determinations are the mean of a great many observations by the author, and give the electro-motive force of the battery as taken on a sine galvanometer. When connected on short circuit the electro-motive force of several of the batteries,

Digitized by Google

and especially the Smee and Woolaston's, will fall off 50 per cent. or more, owing to the formation of hydrogen on the negative plate. Grove's and Daniell's do not fall off, because the hydrogen is reduced by the nitric acid in the one case, and by the oxygen in the other. The internal resistance of Grove's cells is very small, usually below 1 ohm for a pint cell; Daniell's, from 5 to 15 ohms; Smee's, below 1 ohm, varying rapidly with the greater or less disposition of hydrogen.

The electro-motive force of batteries is, within certain limits, very variable, depending on a variety of undetermined causes. It is not much affected by temperature.

Law's Method.—The two elements or batteries to be compared are used in succession to charge a given condenser. Their electro-motive forces are in direct proportion to the charges communicated by them to the condenser. When batteries of very different values are to be compared, a shunt must be used in reading the throw due to the charge current of the larger one. The maximum current of a battery of given surface of plates is obtained when the resistance of the battery is equal to that of the circuit exterior to it.

If we have N elements, the resistance of each being r ohms, and the external resistance of the circuit R ohms, we must arrange the battery in n rows of each $\frac{N}{n}$ elements in series, and these rows we must then connect up parallel with each other. The number of rows will be

$$n = \sqrt{\frac{N n}{R}}$$

The resistance of each row being

$$\frac{N}{n} r = n R \text{ .... ohms.}$$

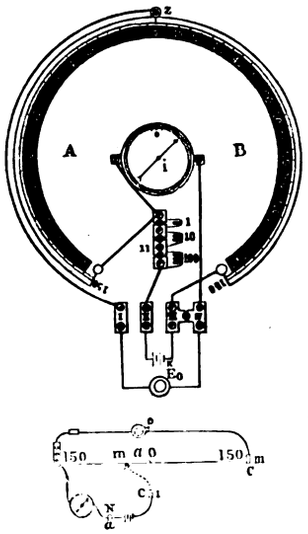

Figure 3.

For measuring electro-motive forces with Siemen's Universal Galvanometer, Professor E. du Bois-Reymond's modification of Poggendorff's compensation method is employed.

The upper diagram of figure 3 shows the connections to be made with the instrument. The needle i is to be brought to the zero point of the small scale by turning the galvanometer G round its vertical axis. The pointer, or vernier, Z, is to be brought by means of the handle g to the zero point of the large scale on the slate disc. The hole between II. and IV. to be left unplugged. Plugs to be inserted in 10, 100, and 1000. The two poles of the battery E_0 (which must be greater than E_1 and E_2) are to be connected with the terminals II. and III. The poles of the battery which is to be compared to E_0 are to be connected to terminals I. and IV. in such a manner that the similar poles of the two batteries are joined to terminals I. and III. and to II. and IV. respectively.

The galvanometer needle will now be deflected, and can be brought back to zero by turning the pointer Z either to the right or the left. Should, for instance, the pointer have to be brought to 30° on the A side, we have the following equation;

$$E_1 = E_0 \frac{150 - 30}{300 + u} \text{ .....(1).}$$

where u is the resistance of the battery E_0.

The battery E_2 is now to be inserted in the place of E_1, and the galvanometer needle, when it deflects again, brought back to zero by moving the pointer Z. If for instance the pointer has to be pushed to 40° on the B side to obtain an equilibrium, we have;

$$E_2 = E_0 \frac{150 + 40}{300 + u} \text{ .....(2).}$$

By eliminating u from equations 1 and 2 we have:

$$E_1 : E_2 = (150 - 30) : (150 + 40) = 12 : 19 \text{ .....(3).}$$

The two electro-motive forces are in the same proportion as the two observed distances of the pointer Z from 150° on the A side of the instrument.

The lower diagram of figure 3 shows the arrangements of the circuits for comparing the electro-motive forces by this method. The more powerful battery E_0 is connected at II. with one end of the resistance coils n, and at III. with the other end of the resistance coil, through the bridge wire. The battery E is connected at IV. with one of the termini of the galvanometer coil, whose other end is connected with one end of the bridge wire, and at I. with the movable pointer, or vernier, Z. The current from E_0 enters the resistance coils at II. and passes through them to the bridge wire, where two paths are open for its return—one *via* the bridge wire direct and the other through the galvanometer, the battery E and the vernier Z to the bridge wire. The current from E enters the bridge wire near the resistance coils n and traverses the former until it reaches the pointer Z, whence it returns. By moving the pointer until the tension is the same at IV. as it is at the junction of the bridge wire and the resistance coils n, no current will flow through the galvanometer.

ELECTRICITY FROM CAOUTCHOUC.—*By M. Demoget.* On one of the most humid days that have recently occurred, I chanced to notice that one of the little air-balloons, so common a source of amusement with children, produced, with the least friction, even under the most unfavorable circumstances, an enormous amount of electricity. It occurred to me to utilize this remarkable property in the construction of an electrophorus, by replacing the plate of resin with a membrane of caoutchouc strained on a metallic circle of 0.8 c.m. diameter. The result surpasses my experience. For it is sufficient to rub circularly with the back of the hand upon the lower surface of the membrane, to place it upon a good conductor, and to rub in the same manner the superior surface, in order to obtain, with an insulated metallic disc of 25 c.m. diameter, brilliant sparks of 3 to 5 c.m. length. In the most humid weather the same effect may be produced by previously slightly heating the caoutchouc membrane. It is well known that if two superposed sheets of paper be rubbed by the hand, after being slightly heated, and then separated in the dark, numerous sparks appear. Sheets of paper may, it has been found, replace the cake of resin in an electrophorus, with, of course, less brilliant results.

MATHEMATICS FOR NON-MATHEMATICIANS.

By William Paget Higgs, LL.D.

Division I.—The Algebra of Constant Quantities.

Tables of Logarithms continued.

TABLES of logarithms are usually arranged to give the mantissæ of the natural numbers, consisting of one to five digits,—that is, from 1 to 10,000; and when the given number, or *argument* as it is termed, has no more than five digits, its logarithm is found in the tables on inspection. But it will often occur that the argument has more than five digits, and the logarithm is found by following this reasoning:—Let us take* the log of 6276153. Now it can be shown that when any two large numbers differ by unity, the increase of the logarithm is sufficiently nearly proportional for all practical purposes to the increase of the number. We look then in the table for the logarithm of 62761 and for that of 62762, and find the mantissæ 0·7976899 and 0·7976988 respectively. The logarithm of 6276200 is then = 6·7976988, and that of 6276100 = 6·7976899. Their difference is 0·0000089. Thus for a difference of 100 in the numbers the difference of the logarithms is 0·0000089. We have then the common rule-of-three sum:—If 0·0000089 added to the logarithm of 6276100 gives the logarithm of 6276200, what must be added to the log. of 6276100 to give the log. of 6276153?

100 : 53 :: 0·0000089 : the number to be added; or—

$$\frac{53 \times 0{\cdot}0000089}{100} = 0{\cdot}000004717.$$

Disregarding the last two figures, we have—

log. 6276153 = 6·7976899 + 0·0000047 = 6·7976946.

Should the first of the figures omitted, however, be higher than 5, or 5 itself, 1 should be added to the number preceding it.

Had the log. of 627·6153 been required, or that of 0·0006276153, we have seen in the foregoing that they would be respectively 2·7976946 and 4·7976946.

Now that we have seen the reason, the rule to find the log. of a given number whose digits are in excess of those given in the table may be stated thus:—Find and write down from the table the mantissa for as many digits as are given. Take the difference between that mantissa and the next greater. Consider the remaining figures of the given number as a decimal fraction, and multiply the difference by this fraction, rejecting as many figures from the right of the product as the multiplier contains. The result added to the lesser mantissa is the mantissa of the logarithm of the given number. Study of the example given above will explain this apparently difficult rule.

The number to be added to a lesser log. to give the log. required is termed the *proportional part*, and is given in the best tables. But as these are variously arranged, we leave the student to consult the instructions accompanying the tables he may

* This and the next example are from p. 125 of Prof. J. H. Smith's "Treatise on Elementary Trigonometry," a work we advise the student to procure.

Digitized by Google

select, content ourselves with imparting to him the *reason* for what he there will be directed to do.

How to find the number to which a log. corresponds we have next to consider. The number may be found exactly in the table, but it may also occur that the exact number is not given exactly. We then state proportionally the difference between the log. next less and that next greater, and the difference between their corresponding numbers :— Thus, suppose we wish to find the number corresponding to the logarithm 3·9212074, the tables give—

log. 8340·8=3·9212077
log. 8340·7=3·9212025

That is,—if a difference of 0·1 in the numbers gives a difference of 0·0000052 in the logarithms, what difference in the numbers will a difference of—

(3·9212074—3·9212025) or 0·0000049

in the logarithms give ?

0·0000052 : 0·0000049 : : 0·1 : 0·094,

which added to 8340·7 gives 8340·794

Rule.—Subtract from the given log. the next less tabular log., and this tabular log. from the next greater tabular log. Divide the first difference by the second or tabular difference, and the first two or three figures of the quotient annexed to the figures of the lesser tabular number will be the number required.

Example—

3·9212074	3·9212077
3·9212025	3·9212025
0·0000049	0·00000·52
	52)49
	·94

and this annexed to 8340·7 gives 8340·749, as before.

The Arithmetical Complement.—This device, discovered by Gunter about 1614, although of very constant use with logarithms, is not by any means an invariable accompaniment of logarithmic tables. Indeed, the addition of the arithmetical complement to every logarithm would render the tables exceedingly unwieldy, and is the more unnecessary since the complement may be very easily calculated. The rule is—*begin at the left hand, and subtract every figure from* 9 *until the last; subtract that from* 10. The reason for the rule is too obvious to need explanation, but an example may aid the student. Thus to find the arithmetical complement to the log. 2=0·30103,

9 9 9 9 10
3 0 1 0 3
6 9 8 9 7

and to log. 7=0·84510,

9 9 9 10
8 4 5 1 0
1 5 4 9 0

Results which the student can verify by reference to the table.

Transformation of Systems of Logarithms.

Hitherto we have considered only the common system of logarithms, or those calculated to the base 10. It is, however, evident that there may be other bases, and consequently other systems of logarithms. The celebrated Baron Napier, the discoverer of logarithms, employed as a base the sum of the following series,* denoting the sum by e.

$$2 + \frac{1}{2} + \frac{1}{2.3} + \frac{1}{2.3.4} + \text{to infinity.}$$

* For an explanation of this term the student is referred to subsequent pages.

The first eight digits of this sum are 2·7182818, and this is the base of what is known as the Napierian or hyperbolic system of logarithms. This system is used in present scientific investigation, and the general principles of the conversion of this system into the common, or of the common into this, will be of service to the student.

Suppose there are any two systems of logarithms whose bases are b and B, and that there is a number n which has x for its log. in the first system and y for its log. in the other system. Then n will be equal to either b^x or B^y, and as we have the first of mathematical authorities—old Euclid—for the assertion that "things equal to the same thing are equal to one another," we may say that b^x is equal to B^y. And if we refer to the principle of the equation given in an earlier page we shall see that (which is or should be self-evident) if we divide the x on one side by the y on the other we still maintain an equation, and that $B=b^{\frac{x}{y}}$ (or dividing by y on both sides we have $B^{\frac{y}{y}} = b^{\frac{x}{y}}$, the same thing). Therefore $\frac{x}{y}$ is the log. of B to the base b; and writing this—

$$\frac{x}{y} = \log._b B,$$

we shall at once see the inverse or reciprocal to be—

$$\frac{y}{x} = \frac{1}{\log._b B.}$$

The reciprocal is taken to allow of readily multiplying both sides of the question by x, whence we obtain the value of y, which is—

$$y = \frac{1}{\log._b B.}\,x$$

And this teaches us that if the log. of any number in the system of which the base is b be multiplied by—

$$\frac{1}{\log._b B.}$$

we shall arrive at the log. of that number to the base B. The multiplier or constant—

$$\frac{1}{\log._b B}$$

is termed the *modulus* of the base B with regard to the base b.

The modulus of the common system of logarithms with relation to the Napierian system is, it follows,

$$\frac{1}{\log._e 10.};$$

and as the numerical value of log. e10 is by calculation 2·30258509, this number divided into unity gives 0·43429448, the modulus of the common system, or the number by which the Napierian logarithm must be multiplied to give the corresponding logarithm of the common system. Similarly 2·3, &c., is the modulus by which a common logarithm is to be multiplied to obtain the corresponding Napierian logarithm.

In practice the reduction of common to hyperbolic logarithms may be effected, but only approximately, by multiplying the common logarithm by 2·3.

When presently more advanced, the student may with advantage return to this chapter, and trace the reasoning embodied in the following formulæ :—

It may be shown that—

$$\log._b B \times \log._B b = 1.$$

For if $b^x = B^y$, then $b = B^{\frac{y}{x}}$

$B = b^{\frac{y}{x}}$; and

$\frac{y}{x} = \log._B b$,

$\frac{x}{y} = \log._b B$. Therefore

$$\log. \; B \times \log._B b = \frac{y}{x} \times \frac{x}{y} = 1.$$

Another exercise, and one by which speed and accuracy in calculation may be gained, is the finding of certain logarithms from other given logarithms.

Given the log. of 2 = 0·3010300 to find the logs. of 64 and 128.

Now 64 is the sixth power of 2; hence by Rule III. the log. of 64 will be six times the log. of 2 The log. of 64 is 1·8061800.

The log. of 128 will be the log. of 64 plus the log. of 2, or seven times the log. of 2.

The following example, adapted from one given by Prof. Smith, affords very useful illustration :—

Given log. 5 = 0·6989700, find the log. of $\sqrt[7]{(6·25)}$.

By Rule IV. the log. of the seventh root of 6·25 is equal to the seventh part of the log. of 6·25. Now we may write 6·25 in the form of a mixed vulgar fraction, as $\frac{625}{100}$, and the resolution of this fraction by logs., according to Rule II., is log. 625 — log. 100, because the form of the fraction indicates that 625 is to be divided by 100; 625, again, is the fourth power of 5, and 2 is the log. of 100. Then—

(log. 625 — log. 100) = 5^4 — 2).

And as the log. of the fourth power of 5 is equal to four times the log. of 5, the expression—

$$\frac{(4 \log. 5 - 2),}{7}$$

which may be read four times the log. of 5 less 2 divided by 7, will give the answer.

Log. 5 = 0·6989700	
multiplied by 4	4
	2·7958800
less 2	2·2000000
divided by 7	0·7958800
	0·1136114

And by similar applications of the four primary rules many examples may be put and solved by the student himself.

MAXIMUM RESISTANCE OF MAGNETIC COILS—*Fourth note by M. du Moncel.*—The author has shown in these notes—(1) That a given helix produces its maximum effect when its proper resistance is greater than that of the exterior circuit in the proportion of 1 to $1 + \frac{c}{a}$; (2) that with the same diameter of coil the helix giving the best results is that in which the wire has such thickness and length that its resistance represents that of the exterior circuit; (3) that the thickness of magnetic helices should be equal to the diameter of the magnetic cores they surround; (4) that their length should be equal to this diameter multiplied by 11, or practically, by 12.

CORRESPONDENCE.

MANAGEMENT OF BATTERIES.

To the Editor of the Journal of the Telegraph:

Agreeably to your request, I note the results of my experience in the management of gravity batteries, and in this I include both forms known in this country; the Hill and Callaud, but not the Lockwood, or any form having a reservoir or magazine, of sulphate of copper crystals.

The Hill battery, an American invention, has been in use for several years, with varying success. Since the introduction of the Callaud, the same variety of opinion prevails, with regard to its utility. While one manager is delighted with the action of either of the forms, another will tell you that he has tried one or both, and they are "humbugs, sir!" and that he has "gone back to Grove—the only reliable battery." Why this diversity of opinion?

Simply, because the philosophy of action of the battery is not understood. A thorough knowledge of its peculiarities will enable any one to work and manage a gravity battery with entire success, and at one-third the cost and trouble that is required in the use of a "Grove."

And the foundation of it all, is this law: *The amount of current flowing to line is in inverse proportion to the resistance in the circuit.* And:

The consumption of material is determined by the amount of current furnished to the line. Or, in other words, the chemical action of the battery is in direct proportion to the work performed.

Hence it follows, that the amount of sulphate of copper converted or consumed in one battery, gives you no result from which to calculate the consumption in a battery on a line of different resistance.

And this brings us to the foundation of all the trouble experienced. The jars have been charged with an arbitrary amount of sulphate of copper, regardless of the resistance of the circuit. The blue vitriol is dissolved by the water, and unless the action of the battery is sufficient to convert the vitriol as rapidly as it dissolved, the blue solution will rise until it comes in contact with the zinc.

In local batteries this is seldom the case; for the total resistance in circuit is but a few units, and the blue vitriol is converted as rapidly as it is dissolved. But batteries on main circuits are so choked back by the line resistance—unless the line is very short—that the vitriol is dissolved with greater rapidity than it is used. Consequently, the copper soon deposits upon the zinc discs, and the battery is ruined.

My rules are: to drop a piece of vitriol of the size of a walnut, into each jar, when it is set up. Let this dissolve, then add small crystals, until the blue solution is, say two inches high, from the bottom of the jar. Instruct your battery man to add the crystals daily, keeping the solution as near as possible at the above height. Wipe off the outside of of the jar, and the inside, above the fluid, daily, to remove the salt of zinc that may be deposited there by evaporation. When the sulphate of zinc solution becomes syrupy, like strained honey, or begins to deposit crystals on the zinc disc, draw off half of it with a syphon, made of twelve to eighteen inches of soft rubber tubing, and fill with fresh water. See that fresh water is added, to replace that lost by evaporation. Keep the battery room warm and dry.

The above rules do not require severe study, or a knowledge of chemistry. They are easily understood, and efficacious. I have yet to find any one so ignorant or stupid as to fail in applying them successfully. And if batteries are managed in this way, they do not need cleaning or taking down. On this company's lines, one battery, working two wires, was set up March seventeenth, 1872; another with four lines, July first, same year. These are both Callaud. A Hill, put up in July last year, is still working beautifully. Several others have been working from six months to one year each. None of them have been taken down, and all are clean, and working well.

It is a mistake, to suppose that the action of a sulphate of copper battery is increased by "crowding it," with an excess of sulphate of copper. So long as there is even a small portion of blue vitriol solution in the jar, its action is as vigorous as if there was a gallon. And I repeat, whenever there is an excess, and the consumption per minute is less rapid than the solution of the crystals by the water, this solution must rise until it reaches the zinc.

The electro-motive force of the sulphate copper battery, being about one-half that of the Grove, double the number of jars is necessary. But the chemical action of the Grove is so much more rapid than that of the sulphate copper, that many more lines can be worked from the former than the latter. The sulphate of copper is sparingly soluble in water, and when you lessen the external resistance, by adding lines, you soon reach the limit of its capacity to supply the blue solution as rapidly as it is needed. The average of lines to be worked economically from the sulphate copper battery is four or five. I prefer the lesser number.

As the internal resistance of a main battery is exceedingly small, compared with that of the line, it may be practically disregarded. I therefore use but one-fourth of a pound of sulphate of zinc to each jar, when setting up a new battery. Callaud's plan of lowering the zinc, to decrease the internal resistance in a main battery, is entirely useless, and from the loosening of the binding screws and consequent dropping of the zincs, this arrangement of hanging the discs is actually a detriment to the battery, instead of an advantage. The only safe way is to hang the zinc the proper height, and then bend over the top of the suspending wire and cut it off; leaving it in the form of a hook on top of the binding screw. I have remedied this trouble, in the zincs used by this company, by casting a copper wire loop in the top of the stem, through which passes a round wooden rod, across the top of the jar. Thus the zincs are all at an equal distance from the bottom of the jar, and the internal resistance of all the jars must be alike. I use the same style and size of zincs, coppers and jars, for main and local batteries.

I am pleased to see that the day is at last dawning when the wasteful and offensive Grove battery will be numbered with many other obsolete things of our early telegraphing.

C. H. Haskins.

Milwaukee, Sept. 16, 1873.

Montgomery, Ala., Sept. 16, 1873.

To the Editor of the Journal of the Telegraph:

Saturday night New Orleans sent us a red message to conductor sleeping car, which would arrive here Sunday morning. In the morning the boy took the message to the depot, three-quarters of a mile from the office, but no "sleeper" had arrived. During the day, New Orleans asked, "Was our red 13th to Conductor Pullman car delivered? Answer quick;" and was answered "No sleeping car from Lynchburg to-day; message not delivered yet." Monday morning the boy again took the message to the depot, and this time was successful in delivering it. About 10 o'clock New Orleans enquired "Was red 13th sleeping car conductor delivered this A. M.," and the reply in the affirmative sent. Here were five messages transmitted, and the messenger compelled to walk three-quarters of a mile twice, causing delay in the delivery of other messages, and the Company receives for all of this service the pitiable sum of fifty cents.

Now don't you think compensation a little more adequate to the service performed would have been more in accordance with the "fitness of things," and that Rule 13 might have been applied in this instance with considerable fitness?

Montgomery.

Hansells, Ind., September 4, 1873.

To the Editor of the Journal of the Telegraph:

A communication signed H, in the Journal of March 1st, claims that three-fourths of the telegraphic bulls arise from spaced letters. Let us examine this assertion, and see if it has any foundation in fact.

If the abstract principle of space, as applied to telegraphic characters, is a cause of error, then it must apply to the whole alphabet; for no letters formed by the combination of two or more dots or dashes, can be written without spacing.

To assert that this principle of *space* is more defective when used in a clear and defined form, as it is used in forming what are called *spaced* letters, than it is when used in a reduced form, as it has to be used, in the formation of nearly all alphabetical characters, is simply absurd.

Again: There is very little, if any, difference in the sound of the instrument in spaces and dashes; the only means of divining whether it is a space or a dash, when made on the instrument, is the back stroke.

The principle of space in sound is inherent in all combinations, and on telegraphic alphabet can be written without it. Space in sound occurs in dashes, the same as in spaced letters. In the former case, the armature is inclined toward the magnet, in the latter it is reversed; but the interval of silence is the same in both.

Every operator knows that spaced letters are the easiest to write, and that beginners learn them more rapidly than any others. They are the musical letters of the alphabet.

But is it a fact, that a large majority of telegraphic errors arise from spaced letters? My experience has been exactly the reverse. Let me give a sample or two. A message was written "Send two bull wheels." The receiving operator got it, "Send two butt wheels." Another message was written "Mary and little one are doing well." The receiving operator presented the expectant father with the following: "Mary and litter are doing well." I think every experienced operator will bear testimony to the fact, that the letters T, and L, and the cypher are more frequently the cause of errors than any others. They are continually being mistaken, the one for the other.

An experience of ten years constant practice at the telegraphic key convinces me that errors do not arise from defects in the alphabet, but from entirely different and extraneous causes. Among them are —poor operators, who, from the very nature of things must do blundering work. Every operator knows that bulls are very seldom perpetrated by first-class operators, and when, in isolated cases, such do occur, they are chargeable, not to inherent defects in the alphabet, but to atmospheric or other disturbance of the circuit. It is human to err, but to charge telegraphic errors to defects in the alphabet, is not warranted by the facts. H. says further,

Digitized by Google

that the European alphabet may be written as rapidly as ours, and can be read much faster. Let us see what ground there is for this assertion.

In the Morse alphabet I find, including spaces, only 143 characters, while in the European there are 182, an excess of 39 over the Morse. In this estimate I have counted only the 26 letters, 10 figures, and the period, comma, interrogation, and exclamation points, as they are all that are in common use. In the above 182 characters of the European alphabet, there are 88 dashes, while in the Morse there are but 49 dashes and spaces together; making an excess of 39 dashes in the European alphabet. Thus it will be seen that the 39 extra characters, which we would be compelled to use, were the proposed change of alphabet made, are all dashes, which are the slowest characters to form with the telegraphic key. H. will have much difficulty in convincing intelligent operators that they can write an alphabet of 182 characters as rapidly as one of only 143, and these 143 the same as the 143 shortest characters in the other aggregate of 182.

But what is to be gained by the proposed change? Has it been shown that telegraphic errors are less frequent in Europe than in America? Can it be demonstrated that inexperienced operators will make less errors with the European than with the Morse alphabet? Certainly not. I have already shown what causes most of the errors in telegraphing. These same causes would bring about the same, or worse results, were we to adopt the European alphabet. The remedy for these difficulties is not in a change of alphabet, but in setting up a higher standard of operative skill and care; and requiring all, who are to be trusted with this important business, to become more proficient.

M. E. W.

To the Editor of the Journal of the Telegraph:

Rule 58 requires free delivery within half a mile of all offices. What course should managers pursue in regard to delivering messages beyond this limit, to parties who *persistently* refuse to pay a reasonably small sum for such extra service—how dispose of their messages? Please reply in next JOURNAL.

C. A. RUNYAN, Manager.

Answer.—Notify such parties, through the post-office, that a message to their address is lying in your office, requesting them to call for it.

ST. LOUIS, Sept. 17th, 1873.

To the Editor of the Journal of the Telegraph:

Party sends message to certain address. Receiving office notifies, "Party moved—not there, &c." If sender wishes to send another or a corrected address, should it not be sent at sender's expense?

E. H. BROWN, Manager.

Answer.—Yes. Instructions of this character should be embodied in a message to the manager of the office receiving, and charged for.

To the Editor of the Journal of the Telegraph:

Please say how many words in following message:—"Smith, New York. Meet me at ferry to-night. (Signed) Jas. Brown, of Wm."

CLERICUS.

Answer.—Such suffixes to a signature as given above should be charged for. They do not come within the scope of the generally understood and necessary appellations of Junior, Senior, First, Second, or Third. The suffix "of William," or any other place, is entirely local in its application, and in use only to a limited extent in a few sections of the country.

To the Editor of the Journal of the Telegraph:

I would like to ask of you a little information about checking San Francisco, Cal., and other lines, you say:

*Boggs, Cal., 30 10 Colusa, Cal., ck. San Francisco.

Why do I check San Francisco—why not Colusa? I checked San Francisco once, on message similar to this. He (San Francisco) said I over-checked him. Please answer how it is and oblige,

E. LEGETT.

Answer.—San Francisco is checked simply as a matter of convenience. Communication by mail with points in the Pacific Division is extremely slow and difficult. It was therefore decided to check all Pacific Division business to San Francisco.

DR. J. H. NELSON.—An invention telling when the line is working, even though the instrument is out of adjustment, is hardly of value at this day. Insulation has become so perfect, and batteries so well regulated to the resistances of the lines, that there can be no excuse for an operator whose instrument is not adjusted. Such an invention, it seems to us, would prove only a premium for carelessness and inattention. Send us a description as you suggest.

C. H. H.—Rule 9 contains the following clause: "Words connected by a hyphen, as found in Webster's Dictionary, to be counted as one word." The word "Lookout," is covered by this rule.

J. W. F.—No part of an address should be charged for. On the contrary, full directions are invited and desired. We have answered substantially the same question many times, of late.

GEO. COLE.—Let us know what numbers of the JOURNAL are necessary to complete your office files, and we will endeavor to supply them. The Company will not pay for binding the volumes of the paper for the use of offices.

SHERMAN, TEX.—An office receiving a transfer, for say, John Smith, care Brown, should deliver it to Smith only. If Smith is absent, the money should be held until his return, unless proper authority is presented for its delivery to Brown.

B.—No notice taken of anonymous communications.

AMERICAN INVENTIONS.

THE cotton gin, without which the machine spinner and the power loom would be helpless, is American. The power shuttle, which permits an unlimited enlargement of the breadth of the web, is American. The planing machine is American. Navigation by steam is American. The mower and reaper are American. The rotary printing presses are American. The hot-air engine is American. The sewing-machine is American. The machine manufacture of wool cards is American. The whole India-rubber industry is American. The band-saw originated, we believe, in America. The machine manufacture of horse-shoes is American. The sand-blast, of which the large capabilities are yet to be developed, is American. The guage-lathe is American. The only successful composing machine for printers is American. The grain elevator is American. The artificial manufacture of ice was originally invented by Professor A. S. Twining, an American. The electro-magnet was invented, and immediately after its invention was first practically applied in transmitting telegraphic signals, by Professor Joseph Henry, an American. The telegraphic instrument introduced a few years later into public use, which has since obtained universal acceptance, was invented by Samuel F. B. Morse, an American.—*Boston Journal of Chemistry.*

FOREIGN TELEGRAPHIC ITEMS

TELEGRAPH EXTENSION IN BRAZIL.

THE Rio Janeiro correspondent of the New York *Herald*, under date of August 25th, writes:

"Our telegraphs are now in progress, the laying of the section of coast cable from Pernambuco to Pará having been commenced at Pernambuco on the 8th of August, and by last accounts was proceeding successfully at the rate of one hundred miles a day, so that by the 30th it should be completed to Pará, after which the section from Pernambuco to Rio will be submerged. Soundings for the latter are being conducted by the Brazilian steam corvette, Vital de Oliveira, and will be finished within a few days.

"The three hundred and eighty miles of telegraph cable for the stretch between Montevideo and the Brazilian frontier arrived on the 9th at Montevideo, and will be laid forthwith. As regards the section between the southern frontier and Rio, all but the shore ends for Santos, Paranaguá, Santa Catharina and Rio Grande are ready in London, and by a recent meeting in Rio of the stockholders of the Platino-Brazilian Telegraph Company the contracts for the remaining parts have been authorized. At the same meeting the working agreements between the Company and the Western and Brazilian and the Montevidean and Brazilian Companies were definitely ratified. By these agreements the Western and Brazilian Telegraph Company takes complete charge of the cables from Pará to Montevideo, and it purposes laying this year a cable from Pará to St. Thomas, to join Brazil, on to the United States.

"The Brazilian Government has given great assistance to the cable companies, both directly and indirectly. Thus, the corvette Paraense was lent for the soundings from Pará to Pernambuco, and to escort the Hooper while laying the cable. The Vital de Oliveira is furnished for the soundings from Pernambuco to Rio, and the Madge is detailed for similar services in regard to the section from Rio to the southern frontier. The telegraphists in the Hoopér are also loud in praise of the assistance received at Pernambuco from the authorities."

AT a meeting of the Board of Directors of the Anglo-American Telegraph Co., held on the 22d August, it was resolved to pay an interim dividend of £2 per cent. free of income tax on the capital of the company, viz., £7,000,000, for the four months ending the 31st July. The register of transfers will be closed from the 10th to the 14th of September, both inclusive, and the warrants for the dividend will be payable on and after the 1st of October next.

The first or statutory meeting of the Globe Telegraph and Trust Company was held on the 27th August. From the report presented it appears that, of the 300,000 shares of £10 each offered to the public, the directors have alloted 224,532 shares, of which 112,266 were for preference shares, and the remainder —112,266—for ordinary shares. Of this number 216,652 were issued in exchange for stock or shares of other companies. The report was unanimously adopted.

The laying of a second cable from England to Denmark for the Great Northern Telegraph Company was completed on Sept. 2, 1873, by Mr. W. T. Henley, of North Woolwich. A cable also from France to Denmark, and one from Denmark to Sweden, have been laid by the same firm during the last few weeks, making an addition of nearly 1,000 miles to the Great Northern Company's system.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 BROADWAY, NEW YORK,
October 1, 1873.

To all Offices on W. U. Lines:

The following changes and additions have been made since the date of the last Circular:

GENERAL INFORMATION.

Auburn, Ala., re-opened; square 267.
Loachapoka, Ala., re-opened.
Shelby Springs, Ala., closed.
Seaview House, West Haven, Conn., closed.
Laurel, Del., closed.
St. Marks, Fla., closed.
Hereafter the "tariff for Other Lines" to Cedar Keys, Fla., will be 150 and 14 from Lake City, Fla.

Until further notice offices will refuse Half-rate business for Pensacola, Fla.

French Village, Ill., closed.
Opdyke, Ill., closed.
Dahlgren, Ill., closed.
Business for Rutland, Ill., will hereafter be checked direct.
Messages may be taken for Rensselaer, Ind., and delivered by stage from Remington, Ind. Charges for delivery, 25 cents.
Fort Harker, Ks., closed.
Carlisle, Ky., closed.
Philadelphia Furnace, Ky., changed to Pennsylvania Furnace.

Half-rate business can now be taken for Shreveport, La.

Business for Hampden, Me. (Upper Corner), can be delivered from Hampden Corner, Me. Charges for delivery, 25 cents.
Deer Park, Md., closed.
Elba, Mich., re-opened.
Blissfield Junc., Mich., closed.
Fayette, Hillsdale Co., Mich., closed.
Hereafter the "tariff for Other Lines" to Morenci, Mich., will be 25 and 2 from Toledo, O.
The office at Fayette, Mo., will hereafter be in square 409.
Bethlehem, N. H., closed.
Crawford House, N. H., closed.
Fabyan House, N. H., closed.
Glen House, N. H., closed.
Twin Mountain House, N. H., closed.
Mt. Washington, N. H., closed.
Mt. Washington Depot, N. H., closed.
Profile House, N. H., closed.
Waumbeck House, Jefferson, N. H., closed.
Deal, N. J., closed.
Chittenango Springs, N. Y., closed.
Catskill Mountain House, N. Y., closed.
Little Mountain, O., closed.
The P. O. A. of Glenwood, O., is Ava, Noble Co.
Cresson Springs, Pa., closed.
Lincolnville, Pa., closed.
Milford, Pa., re-opened as an Other Line office; tariff 20 and 2 from Port Jervis, N. Y.
Business for Wiconisco, Pa., will hereafter be delivered from Lykens, Pa.; charges for delivery, ten cents.
The P. O. A. of Buena Vista, Butler Co., Pa., is Peachville, Pa.
Watch Hill, R. I., closed.
Mossy Creek, Tenn., closed.
Mineola, Texas, is now a W. U. office, square 470; check direct.
Jordon's White Sulphur Springs, Va., closed.
Livingston, Va., closed.
Rockbridge Baths, Va., closed.
Berkeley Springs, W. Va., closed.
Elizabeth, W. Va., closed.
Stillwater Junc., Wis., closed.
Highgate Springs, Vt., closed.
Yellow Sulphur Springs, Va., closed.

CUBA CABLE BUSINESS.

We are notified that communication by cable to Martinique, St. Lucia, St. Vincent, Grenada, Barbadoes, Trinidad, Demerara and Berbice is interrupted. The cable between Dominica and Martinique is broken.

WILLIAM ORTON,
President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Sept. 24th, 1873.

On and after October 1st, Columbia, Tenn., will be added to the list of money order offices in J. B. Tree's district.

MILLERSTOWN, reported in last issue of the Journal as having been added to the list of money order offices in C. O. Rowe's district, is in Butler Co., Pa.

G. H. MUMFORD,
Vice-President.

INFORMATION WANTED.

Mr. M. E. BOOTH, operator at Alliance, Ohio, desires the address of JAMES C. TOWNS. When last heard of, Mr. TOWNS was operating at Brookville, Kansas.

TELEGRAPH IMPROVEMENTS IN PENNSYLVANIA.

The *Reading (Pa.) Eagle* of September 23d, states that the Western Union Telegraph Company are making considerable improvements in that vicinity, by placing large, straight and nicely dressed poles along the line of their wires, in lieu of the crooked ones heretofore in use. The company are adding two new wires along the line from Philadelphia to Pottsville, and from Reading to Harrisburg, and replacing the two old wires with new ones. Instead of continuing down the turnpike as at present, the wires will be taken across Madison bridge, a short distance below that borough, and run down the Schuylkill road to Phœnixville, where they will recross to the turnpike again.

New offices will be opened at Phœnixville and Royer's Ford. The Pottstown office will be refitted and the new wires put in. The rapidly increasing business of the company along this route render these improvements and additional facilities necessary. Mrs. H. L. Brower, the polite and very obliging operator at Pottstown, deserves credit for the faithful and very accurate manner she attends to the duties of her position. During the many years she has been on duty there as operator, not a single word of complaint has ever been entered or fault found with her. The lady always appears pleasant, is very attentive, and gives universal satisfaction to all who have business with the office.

BORN.

ARTHUR.—At Hanover, O., Sept. 15, 1873, to J. G. Arthur, Manager W. U. Tel. Office, a daughter.

KELLY.—At Huntington, Pa., Sept. 21, 1873, to James Kelly, Manager W. U. Tel. Office, a son.

MARRIED.

GREENE—BURCH.—At White Pigeon, Mich., Sept. 12, 1873, by Rev. Byron Russell, A. A. Greene, Manager W. U. Tel. Office, Windsor, Mo., to Miss Frank Burch, of Carthage, Mo.

DIED.

PHILLIPS.—At Providence, R. I., Sept. 14, 1873, Irving Adderman, eldest son of Walter P., and Francena Adelaide Phillips, in the fifth year of his age. Also, in same place Sept. 16, 1873, Eugene Dunbar, infant son of Walter P. and Francena Adelaide Phillips, aged one month.

Digitized by Google

TELEGRAPHIC INSTRUMENTS AND MACHINERY AT THE CINCINNATI EXPOSITION.

One of the most complete and perfect features of this year's Exposition is the collection of telegraphic instruments and their various adaptations. No finer display of the kind has ever been made in this country, and to any one interested in the progress made in electric science no more favorable opportunity for study could be desired. Important discoveries and improvements are shown, which are now in successful use, and of which the ordinary public has never even heard. In fact, the mysteries of telegraphy are something which very few people beyond operators know anything about. Yet the initiated few are not idle. Every year is prolific in improvements of permanent value, which serve to expand the telegraphic service of the country as its growing necessities require. A large number of these inventions may be seen in operation in the Main Hall, a full description of which would fill columns. It is only possible, in this short article, to refer briefly to the leading ones.

The American fire alarm telegraph is exhibited from New York. It is by the same inventors, and essentially the same system as that now in use in this city. There is difference, however. The alarm given by the automatic system strikes directly upon the bells; whereas by our present system it is turned into the central station, and there repeated by an operator, which consumes more or less time. The striking of the numbers is regulated by clock work in the alarm boxes. This mechanism is set in motion by the mere pulling down of a brass hook or knob, which is plainly visible on opening the outer door of the box—and this action is all that is necessary to create an alarm of fire. So perfect is this mechanism that it is utterly impossible for any other than the correct signals to be transmitted, and when once started, it can in no way be interfered with until it has performed its entire work. If by chance two alarms should be turned in simultaneously, one would wait until the other was finished before striking. The connection between the alarm boxes and the bells is made by a beautiful piece of electro-mechanical work called an automatic repeater. The display embraces a complete circuit, representing several alarm boxes, as well as the central and other fire stations. About four thousand dollars were expended in making and putting in place the machinery of this single exhibition.

Another display of novel and interesting instruments is made by an association of this city. "Semaphore" or repeating signal is an ingenious contrivance for dispatching trains, signaling at station yards, junctions, crossings, curves, &c. It is self-operating and instantaneous. By a mere touch of the instrument a white or red signal can be raised at a point a mile distant. Another signal improvement of this nature is an automatic clock signal, which uses the track itself as an electrical conductor for operating semaphoric signals. This system is designed more especially for double track roads, and absolutely prevents trains following each other on the same track—except within a stated distance. In case a train breaks in two, and a portion of it is left standing on the line, the signal will indicate the fact to the following train.

In this same collection is shown an instrument which looks like a combination of a melodeon and a sewing machine. Each key is lettered, and the operator, generating electricity by a pedal, fingers off a dispatch which is perfectly printed at the other end of the line. Other telegraphic printing instruments are shown, among which is the dial plan in present use by our police. The exhibitors of this collection have the contract for running the police telegraph of this city.

An interesting piece of mechanism is shown, which was made by Wheatstone, the celebrated English electrician, for testing the amount of resistance on telegraph lines. By some mysterous means a break in the line can be located from any distance to within a hundred feet. Should the Atlantic cable suddenly part, this little instrument could direct a ship to the very spot where the difficulty lay.

A regular set of telegraphic instruments, made of solid silver, and worth $2,000, attracts considerable notice. It is exhibited by a New York company, who also have in operation the wonderful little gold and stock telegraph printing instruments, by which quotations are printed simultaneously every day in our leading banking houses. A variety of specimens of submarine cables, and a large collection of telegraphic machinery of every description, make this a very full and interesting display.

Among the other inventions is what is called a "double Morse telegraphic alphabet," patented by Mr. Nicholson, of this county, which, it is claimed, insures greater speed and simplicity in the transmission of words than the Morse alphabet. Improvements are shown in galvanic batteries—one by which the consumption of material is greatly reduced. A copper spiral wire is introduced into the jar, which, by some unknown means, serves to retain the intensity of the copperas and zinc agents much longer than in the old jar.

The aggregate value of the various electric instruments and machinery entered by the various exhibitors is estimated at $12,000.—*Cinc. Gazette.*

THE ELECTRIC LIGHT.

Up to the present time, as is well known, the electric light has been used only for lighthouses, as an electric sun illumination for signals, or on the stage, where a strong light may be required without regard to cost; but thus far it has been quite impossible to employ it for lighting streets or houses. By the old method the electric spark was passed between two points of charcoal, each attached to a copper wire connected with an electro magnetic machine. The disadvantages attending this mode consisted in the facts that for each light a separate machine was required, and that the light so obtained, although very powerful, was impossible to be regulated, besides being non-continuous, owing to the rapid consumption of the charcoal points from exposure to the air. All these difficulties, Mr. A. Ladiguin, of St. Petersburg, Russia, has tried, and apparently overcome most successfully. By this newly invented method, only one piece of charcoal or other bad conductor is required, which, being attached to a wire connected with an electro-magnetic machine, is placed in a glass tube, from which the air is exhausted, and replaced by a gas which will not at a high temperature combine chemically with the charcoal. This tube is then hermetically sealed, and the machine being set in motion by means of a small steam engine, the charcoal becomes gradually and equally heated, and emits a soft, steady, and continuous light, which, by a most simple contrivance, can be strengthened or weakened at the option of those employing it, its duration being dependent solely on the electric current, which of course will last as long as the machine is kept in motion. Taking into consideration the fact that one machine, worked by a small three horse power engine, is capable of lighting many hundreds of lanterns, it is evident that an enormous advantage and profit could be gained by the illumination of streets, private houses, public buildings, and mines, with the new electric light. In the latter, it must prove invaluable, as no explosion need ever be feared from it, and these lanterns will burn equally as well under water as in a room. Without mentioning the many advantages this mode of illumination has over gas, which by its unpleasant odor and evaporation is slowly poisoning thousands of human beings, and from which explosions are frequent, we can state that, by calculations made, this electric light can be produced at a fifth of the cost of coal gas. We hope shortly to place before the public more complete particulars, as well as reports of further experiments which are proposed to take place in Vienna, Paris, and London.—*Golos, and Journal of Society of Arts.*

Is the Electric Current an Ether-Motion.—*By M. Antonio Roiti.*—As a test of the theory that the galvanic current is a motion of the luminiferous ether, M. Roiti describes an interesting experiment. If the theory is correct, the velocity of propagation of light in a body through which a galvanic current passes must vary with the direction of the current. The motion of the ether, in form of galvanic current in the body, will be added to that of the light waves, or subtracted from it, according to the direction; and such a difference may be observed in the interference-fringes of a ray of light. Solar rays, united in a focal line of a cylindrical lens, and made parallel by a spherical lens, were sent through a glass case having two divisions; pasing through two slits parellel to the focal line of the cylindrical lens, and about the thickness of the partition apart. In exit the two rays interfered, and interference-fringes were observed. The case contained a solution of sulphate of zinc and four amalgamated zinc plates, which served as electrodes. They rested against the front and back walls of the divisions of the case, but were somewhat narrower than these, that passage might be afforded to the light rays which went close by the partition. The electrodes were so connected with the battery that the current had opposite directions in the two divisions. The currents were gradually increased in strength, till at last twenty Bunsen elements were used. "The fringes were displaced but the displacement was slow, and *independent* of the direction of the current. It came always from that division which, containing a greater quantity of liquid, offered less resistance. In short, it was, no doubt, an effect of heat developed by the electric current. And when the resistances in both columns of liquid were made equal, I found it impossible to perceive any difference in the fringes, whether the circuit was closed or broken, or whether the plates were neared to each other or withdrawn. I must remark, however, that the fringes were very small, and that my apparatus did not permit of enlarging them; further, that the floor shook, from noises outside. But in no case was there displacement the breadth of a fringe. It may be inferred, that if the galvanic current is a flow of ether, the velocity of the ether must be very small; more exactly, if we take the velocity of light as 298,000 kilometres per second, the wave-length 0·0006 m.m., and the length of the entire column of liquid 90 c.m. (the case was 45 c.m. long), the velocity in question must be less than 200 metres in the second,—a result which makes the hypothesis very improbable."

In Russia, every endeavor is being made by the government to advance and diffuse knowledge in the arts and manufactures. With this object in view, fifteen exhibitions have, within the past few years, been held alternately at St. Petersburg, Moscow and Warsaw.

ONE DOLLAR PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, OCTOBER 1, 1873.

THE TELEGRAPHERS' MUTUAL LIFE INSURANCE ASSOCIATION.

The acknowledgment of receipts and other matter pertaining to the insurance association, intended for this issue of the JOURNAL, is unavoidably delayed, but will appear in the next number.

We regret to announce the death, at half-past seven o'clock this morning, after a brief illness, of Mr. E. S. Keep, Manager of the Albany, N. Y., office. Mr. Keep, although a comparatively young man, was one of the oldest and most highly esteemed men in the service, of gentle and winning manners, and a thorough Christian gentleman. His early death will be deeply regretted by all who knew him, and his family will have the heartfelt sympathy in their great affliction of all in the service.

We publish on our first page an exhaustive article on the Measurement of Electro-Motive Forces, for which we are mainly indebted to the valuable work on electric measurements and electrical tables by Latimer Clark and Robert Sabine.

BLANK No. 26, requesting customers to call for dispatches, has been printed upon postal cards, and can be had by order upon the supply department.

Our supply of the edition of July 1st, 1873, is completely exhausted. Superintendents and others who may have extra copies of that date will confer a favor by forwarding them to this office.

The Anglo-American Telegraph Company contemplate the discontinuance, after January 1st, 1874, of their agency at New York.

All communications respecting accounts in error with the Long Branch, N. J., office for the months of June, July, August and September, should be addressed to Superintendent Hinchman, No. 145 Broadway, New York.

THE YELLOW FEVER AT SHREVEPORT, LA. FAITHFUL TELEGRAPHERS.

The yellow fever epidemic which appeared at Shreveport, La., in the early part of September, has been of the utmost severity, the deaths having averaged sixty per cent. of those attacked, thirty to forty dying daily. As many of the inhabitants who could, fled; but, at present writing, it is estimated that at least 1,000, out of a population of 3,000, are either sick or convalescing. In proportion to their number telegraphers have suffered exceptionally.

On the 16th President Orton received the following despatch from General Superintendent Van Horne, which shows clearly the condition of affairs in that unfortunate community:

"LOUISVILLE, KY., Sept. 16—2 o'clock.

"When the fever made its appearance at Shreveport we had there two operators besides the manager. One left immediately. George J. Rae, manager, and Thomas M. Jackson, operator, remained at their posts till stricken down. Mr. Jackson died on Saturday and Mr. Rae yesterday. Operator Buchanan, of Meriden, tendered his services, and reached Shreveport on Wednesday, but when Mr. Rae was taken sick on Thursday, Mr. Buchanan returned home, and is now ill there. Operator H. C. Davis came from New Orleans on Sunday, and is now alone on duty in the Shreveport office. Our repairer has the fever, but will probably recover. Alfred Saville, although unacclimated, has gone to help Davis, and will probably reach Shreveport to-night. Rae and Jackson are supposed to have been the main supports of their respective families. Rae's father is an invalid, and Jackson's mother is a widow. Our banker, Mr. George A. Pike, and operator Davis did all they could for the relief of Mr. Rae. Jackson died before Davis reached there, but he received kind attention from Mr. Pike. Nearly all who were able to leave the town have left, but there are fully 600 cases of fever there now, and the number of people who are well is not sufficient to take care of the sick. The fever is unusually fatal, and it is believed by many to be the Mexican *vomito*, and to have been introduced by the employees of the Transatlantic Circus. It attacked persons who had yellow fever in Shreveport in 1867. Contributions are coming in slowly from all parts of the country. Physicians and nurses are badly needed. The condition of the town is simply heart-rending, and the suffering is something fearful to contemplate."

Immediately upon the receipt of the dispatch from Mr. Van Horne, President Orton issued the following order to the superintendents of the Western Union Telegraph Company throughout the country:

"Instruct all the managers to send free messages relating to the relief of the citizens of Shreveport, and at the request of the Governor, or United States Senators of Louisiana, direct contributions of money to be received and transferred by telegraph without charge."

In New York, and throughout the country, contributions in money were freely made, and as rapidly as the funds were placed in the offices of the Western Union Telegraph Company, transfer was made at Shreveport, free of all charges.

The direct aid thus afforded by the Company is beyond computation, and their liberality will not soon be forgotten by the public.

The relatives and friends of Messrs. Rae and Jackson, who died at the post of duty, have the sympathy of the Company and of the whole fraternity in their affliction. Telegraphers will remember with pride that they have had associates whose faithfulness and devotion to duty arose superior to any feeling of personal danger.

The services of Messrs. Buchanan, of Meriden, Miss., Saville, of Memphis, Bernard, of Cincinnati, and Davis of New Orleans, who volunteered for duty at Shreveport, cannot be commended too highly. The fact that the three former were unacclimated, places their conduct in the more favorable light. Mr. Davis, as will be seen from the following letter from Superintendent Compton, is an old hand at fighting "Yellow Jack." These gentlemen have rendered good service in the cause of humanity, and have fully demonstrated their devotion to the interests of the Company. The epidemic is now slowly abating, and it is to be hoped that they will escape unscathed.

JACKSON, MISS., Sept. 16th, 1873.

To the Editor of the Journal of the Telegraph:

A noble example should not be suffered to remain in obscurity, or a noble deed go unrewarded. Two years ago, when the city of Natchez, Miss., was visited by that terrible scourge "yellow fever," Mr. Morris, our manager, was one of its many victims. H. C. Davis, one of our old operators (not then in the Company's service) volunteered to fill the place. Reporting at Natchez for duty, he was shortly prostrated by the disease, but recovered. The nearly unparalleled calamity that has this year fallen upon Shreveport, La., deprived the unfortunate citizens of the then much needed telegraph, and for some days the office was closed. Henry C. Davis (then employed in New Orleans), again taking his life in his hand, volunteered to go to Shreveport, a city plague-stricken—for yellow fever is no name for the malignant disease now raging, if the reports of persons falling dead in the streets is true. I know that young Davis seeks neither thanks nor reward, and doubt not but that he would shrink from a public notice of his noble act. Our fraternity have given many instances of self-sacrifice, yet, in an experience of 25 years, I do not remember of seeing or hearing of the thanks of a community, or the recognition by the Company, of such noble service.

J. COMPTON, *Asst. Supt.*

THE DUPLEX TELEGRAPH.—The American Institute of New York has awarded "The Great Medal of Honor" to Joseph B. Stearns, for the invention of the duplex telegraph, which has made a revolution in telegraphy in the United States, and has been adopted by the Postal Telegraphs in this country. The American Institute is a very old and eminent society and is understood to have made the present award after a most careful and exhaustive examination as to the novelty and value of the invention. Only two other medals of this class have been issued by the Institute since its foundation, the conditions upon which they were awarded being such as to exclude all inventions and improvements except those of the highest importance—viz., first, the machine or process must have superseded all others previously employed for a like purpose; second it must have created a revolution in the art or business in which it is employed.—*London Times, Sept.* 13, 1873.

ADOPTION OF STEARNS'S DUPLEX SYSTEM BY THE BRITISH GOVERNMENT.

The British Postal authorities have adopted Stearns's Duplex Telegraphs, and are putting the apparatus on their lines as rapidly as possible. Mr. Culley, the Engineer-in-chief of the Postal Telegraphs, states, under date of August 18th, that the Postal Telegraph Department is using Mr Stearns's system on the following circuits:

London to Liverpool,
London to Manchester,
London to Bristol,
London to Birmingham,
London to Edinburgh,

with perfect success, and that he is preparing to extend the system to other important circuits as soon as arrangements can be made. Mr Culley also states that it has not been found possible to work satisfactorily circuits approaching one hundred miles in length in both directions at the same time except by Mr. Stearns's method.

Frank Ives Scudamore, Esq. C. B., the efficient Head of the Post Office Telegraphs, also states that Mr. Stearns's system of duplex working has been applied to the Wheatstone automatic instruments, used upon their circuits, with the best possible results.

The duplex is also being worked upon the lines of the Anglo-American Company between London and Valentia.

The following letter from Mr. Stearns appears in the money article of the London *Times* of September 1st.

"Sir:—In *The Times* of August 27 you call attention to a system of duplex telegraph,' by means of a condenser, which enables the operator to send messages through the cables in opposite directions at the same moment,' and that the electricians of the Eastern Telegraph Company had surmounted all obstacles and applied the system to certain of their cables, &c.

"As the system in question is mine, and mine alone, I cannot allow the credit of the invention to be given, even unintentionally, to others. Copies of my English patents were sent to the electricians of the Eastern Company some months ago, and my system explained to them by an officer of the Postal Telegraphs as long ago as last March, and I do not believe that they have knowingly claimed the credit of the invention. To the credit of 'surmounting the difficulties' in applying the system to their own cables, they are justly entitled certainly; but if they claim more they do me injustice. The system is secured to me by letters patent in Great Britain and the Colonies, in nearly every country in Europe, and in the United States. It as been adopted by the Postal telegraphs and is worked between London and all the larger cities in England, and its use is being constantly extended. It is also working upon the lines of the Anglo-American company, between London and Valentia, upon the prineipal lines in the United States, Canada, and Nova Scotia. I put it into successful operation upon cables 340 miles in length, between Cape Breton and Newfoundland, in August, 1872.

"It can be worked in connection with any of the old and well-known systems, like the Morse, the Needle, the Wheatstone, the Hughes type-printer, the Mirror, or any other, and this last circumstance adds greatly to its value, as all the apparatus now on hand, and in use by the various governments and Companies, can still be used by merely adding the Duplex attachments, which are not expensive.

"The system has not yet been successfully applied to long cables like the Atlantic, but I have no doubt that, with further experience, cables of any length may be worked.

"I am, Sir, your obedient servant,
"J. B. STEARNS.

"26 Old Broad street, Aug. 30."

ANNUAL MEETING OF THE GOLD AND STOCK TELEGRAPH COMPANY.—ELECTION OF OFFICERS.

The annual meeting of the Gold and Stock Telegraph Company was held at the office of the Company, 61 Broadway, in this city, on Tuesday, the 23d ult. The old Board of Directors was reëlected, with the exception of the substitution of Mr. George B. Prescott in place of Mr Horace F. Clark, deceased. The following constitute the Board for the ensuing year: Messrs. Tracy R. Edson, Wm. Orton, George B. Prescott, Joseph M. Cook, Marshall Lefferts, James H. Banker and Alonzo B. Cornell.

At a subsequent meeting of the Board of Directors, Marshall Lefferts was reëlected President, Tracy R. Edson was elected Secretary and Treasurer, and an Executive Committee, consisting of Messrs. Orton, Banker, Edson and Prescott, appointed.

TRUE SUCCESS IN LIFE.

By Ray Palmer.

In a few familiar, but pointed words, the author of this volume offers a series of friendly counsels to youthful readers on topics relating to the formation of character, and the responsibilities of life. The importance of self-culture is enforced by a variety of apt and judicious considerations, showing the duty of constant improvement in the intellect, and the heart, and in personal manners and bearing. The author laments over the small number of those who, after leaving school, take any systematic care to secure their mental growth. It is a great mistake, he insists, to suppose that intellectual pursuits should then entirely give place to the duties of active life. There cannot be a greater shame than thus to convert the beautiful possibilities of existence into a mere mechanical routine, in which there is the toil of motion, but no more progress than in a treadmill. He admits the difficulties of the case. It is not an easy thing for an apprentice or clerk to find time for the improvement of his mind. He is often obliged to give every moment from morning till night to the shop or the counting-room. But this is the fault of our prevailing system, and is wholly wrong. The eagerness for gain usurps the whole of life, and imprisons it in one dull round of care and toil. This devotion to Mammon is the ruin of the mind. Not less earnestly does the author urge the necessity of Christian principles to the accomplishment of the great purposes of life. True success can be attained only by obedience to the precepts of religion, and the struggles and discipline which belong to genuine goodness. In the preparation of this work, Dr. Palmer has shown himself the sincere and intelligent friend of youth. His counsels are temperate and judicious. He presents no false views of life, nor attempts to beguile the fancy by false and inflated eloquence. His language is as grave as it is earnest, and derives a peculiar impressiveness from the force of truth and freedom from pretence.

The United States steamer Tuscarora has sailed from Victoria, for Cape Flattery, to commence soundings for the cable to Japan.

LETTER FROM PRESIDENT ORTON, CORRECTING ERRONEOUS STATEMENTS IN THE NEW YORK TIMES.

The New York *Times* of September 17, contains the following letter from President Orton:

"An editorial in The Times of the 9th inst., headed "Stock Watering," contains the following: "(1) In the United States, telegraphing to the private individual is dearer than in most civilized countries, and so dear as to prevent largely its use except for business purposes. (2.) The average charge of the Western Union Company in 1872 was seventy-two cents for each message. (3.) This enabled the Company to pay six and a half per cent. dividend on the nominal capital. (4.) But if the capital had not been watered, and represented the actual cost of the property, the Company could have reduced their rates to an average of twenty-four cents, and still paid six and a half per cent dividend." Believing that you do not intend to do an injustice to the Western Union Company, nor to give currency to erroneous impressions concerning the telegraph business of the United States, as compared with that of other countries, I ask permission to reply to the statements above quoted, as follows:

1. Sixty per cent of the cost of carrying on the telegraph business of the Western Union Company is paid for labor. The wages paid are more than double the rate allowed by the Governments which control the business in other countries. Wire, and nearly all other materials used in constructing and operating telegraph lines in the United States, cost from forty to sixty per cent. more here than in any European country. Ten miles of line must be erected and maintained in the United States to reach the same number of population that in Europe may be reached with one mile. Taking these facts into account, it seems clear that the telegraph service is necessarily much more expensive in the United States than in Europe. But, notwithstanding the less favorable conditions under which the business is carried on, the average message costs no more in the United States to-day than it does in Europe.

2. The receipts of the Western Union Company per message in 1872 were not seventy-two cents, as stated, but sixty-two cents. The average receipt per message of all the Governmental telegraphs in Europe for the year 1870 was forty-five cents. This was the average per message paid by those who used the telegraph. But the average cost per message to the Governments which carried on the business was sixty-one cents, the deficiency having been paid by taxation. Since 1870, the average cost per message in Europe, whether to the sender or to the Governments which carry on the business, has not been reduced. On the contrary, the excess of expenses over receipts seems to be increasing, and in order to check this tendency and to lessen, if possible, the annual deficit, the French Government last year advanced the rates on messages in that country from twenty to forty per cent., and I venture the prediction that an advance of rates will be made by other European Governments within a short time. The managers of the Western Union Company have not failed to give to the subject of message rates the most careful consideration. They have desired to give the public the benefit of rates as low as appeared consistent with their duty to the stockholders. In the Fall of 1869 the attempt was first made in this country to establish a telegraphic tariff system, based on air-line distances. In consequence of the reductions then made the receipts for 1870 were less by about $200,000 than for the preceding year, while the expenses were increased more than $300,000, and the net profits diminished more than $500,000.

Digitized by Google

There was an increase of over 1,000,000 in the number of messages sent. A year later another important reduction was made by the establishment of the night message system at half rates. On the 1st of February, 1873, $2.50 was made the maximum rate for messages between all points on the Western Union Lines. This was equivalent to a reduction of fifty per cent. on the entire telegraphic business between the Atlantic and Pacific coasts. The reduction was also quite large on the rates between the Southwestern and Northeastern States, and between the stations west of the Mississippi and Missouri and those in the Atlantic States. On the 1st of July, 1873, a further reduction was made by the more complete substitution of the air-line system of rates, first introduced in 1869. As a result of these reductions the average rate per message in the United States for the year 1873 will be considerably less than in 1872. I have just completed an examination of the reports for the month of July last, which shows that the average receipt per message was fifty cents, and this average is not likely to be exceeded hereafter.

3. The Western Union Company did not pay a dividend of six and a half per cent. either on its nominal or actual capital for or during the year 1872 No dividend whatever has been paid to the stockholders of this Company during the last three years.

4. The question whether the capital has been watered, or represents the actual cost of the property does not, therefore, seem to have any bearing upon the rates charged during that period. But if the rate had been an average of twenty-four cents per message, instead of enabling a dividend of six and a half per cent. to be paid on the actual cost of the property, as you state would have been the result, we should not have received sufficient revenue to pay the expenses of conducting the business.

I have now before me an exhibit of the cost per message for operators' and messengers' salaries for the last five years, as follows: 1869, 28 cents; 1870, 26½ cents; 1871, 25 cents; 1872, 24½ cents; 1873, 23½ cents. The cost per message of the messenger service has not varied more than one-quarter of a cent during this time,

The cost per message of maintaining the lines, exclusive of superintendence, that is to say, the labor and material expended in reconstruction and repairs during the same period, is as follows: 1869, 8¾ cents; 1870, 8¼ cents; 1871, 7¾ cents; 1872, 7½ cents; 1873, 9¼ cents.

It will be seen by this exhibit that no amount of telegraphic business which it would have been possible to handle would have yielded at twenty-four cents a message sufficient money to pay the salaries of operators and messengers, and the cost of maintaining the lines.

Any considerable increase in the number of messages involves the provision of additional wires, and as the mileage of poles and wires increases, the aggregate cost of maintenance increases, so that the cost per message of maintaining 100,000 miles of wire is not materially reduced when the mileage of wire and the number of messages have been increased fifty per cent.

I have said nothing of other expenses quite as inevitable in the conduct of the business, such as printing and stationery, rent, light and fuel, office furniture, instruments and battery, law expenses and damages, and State and local taxes.

The facts connected with the growth and conduct of telegraphic business in the United States and other countries are so important as to merit more careful study than has heretofore been given, and I am glad to see that *The Times* is disposed to consider them. One of the first results of intelligent and impartial investigation of this subject will be to satisfy the inquirer that the cost per message of sending telegraphic communication by any of the processes now employed is much greater than has been supposed, and that the cost does not diminish in the ratio of the increase in the number of messages.

Whatever mistakes may have been made, the present managers of the Western Union are not liable to public censure either for "stock watering" or for the payment of excessive dividends to stockholders, as they have neither increased the capital stock nor made a distribution of profits. But they have done this: They have constructed more miles of telegraphic line and wire than all other parties in the United States in the same time, have steadily reduced their rate of charges, and have improved the character of the service, and the figures for July, 1873, which I have given, show that they now charge on the average eleven cents less per message than the average cost of transmitting a message on the Continent of Europe in 1870.

Very respectfully,

WILLIAM ORTON.

EXECUTIVE OFFICE, WESTERN UNION TELEGRAPH COMPANY, NEW YORK, Sept. 16, 1873.

VIENNA IMPERIAL ACADEMY OF SCIENCE.

Professor A. de Waltenhofen has established, by the aid of the calculus, the following theorem:—The magnetizing power of a spiral is proportional to the product of the intensity of the current multiplied by the sum of the cosines of all the angles formed by the axis of the magnetized coil and the right lines directed towards the extreme points of this axis from a point on each turn of the spiral, situated in the plane of the axial section. This theorem is available only in the supposition that the axis of the magnetic coil is in the same direction as that of the helix and that the intensity of the current does not exceed limits within which it remains proportional to the electromagnetic force. This theorem confirms and explains the results of the experiments of MM. Lenz and Jacobi on the relations between the electro-magnetic power and the number, amplitude, and arrangement of the turns of the metallic wire. The construction proposed by M. Haedenkamp for the attractive action, and that proposed by M. Wazsmuth for the magnetizing action of a spiral, are both only particular applications of the theorem of Waltenhofen. The sum of the cosines of a cylindrical spiral, calculated according to this theorem, serve to determine the relation between the magnetizing power of two given spirals, and here again the results of calculation coincide with those of experiment.

MM. Boltzmann and Roimch have proceeded with their experimental researches on dieletric constants of insulating bodies, using for this purpose an electromagnetic diapason, the oscillations of which charged at short intervals alternately with positive and negative electricity, the conducting ball of which they wished to find precisely the action on the dielectric ball. They have been able also to eliminate that disturbing cause termed by Faraday electric absorption, and to obtain constants sufficiently concordant with those deduced from experiments with the condenser, as the following comparative table shows:—

DIELECTRIC CONSTANTS.

Substances.	By the mutual action of the balls.		By the Condenser.
Sulphur	3.857	3.904	3.84
Hard Gum	3.550	3.400	3.15
Parrafline	2.310	2.280	2.32
Colophane	2.450	2.470	2.55

TRANSATLANTIC LONGTITUDES DETERMINED BY THE U. S. COAST SURVEY.

A paper read before the American Association for the Advancement of Science, at Portland.

The exact determination of the longitude of some point in the Coast Survey, from the principal observatories of Europe, is a matter of the first importance. The methods of moon culminations, of lunar occultations, and of chronometer transportation, formerly employed, yielded results whose degree of accordance still left much to be desired. The success of the transatlantic cable rendered it possible to use the telegraphic method, which was promptly done in 1867, when the longitude between Harvard College Observatory and Greenwich was determined, under the direction of Dr. B. A. Gould, through the Ireland-Newfoundland cables. When the French cables from Brest to St. Pierre, and thence to Duxbury, were laid, a second determination was made, under the charge of Assistant G. W. Dean, in 1870, in order to check the accuracy of the method; but as no cable was then laid between Brest and England, the link to connect with Greenwich was still wanting, and, carrying it by the French longitudes to Paris, and thence to Greenwich, an indifferent agreement with the former value was obtained. The missing link was supplied in 1872 by Prof. J. E. Hilgard, who at the same time repeated the transatlantic determination. The plan of operations was to receive at Brest simultaneously the time signals from America, from Greenwich and from Paris; thus referring the American station at once to both observations, and obtaining at the same time the difference of longitude between the latter. Next, the Brest observer successively visited, with his own instruments, all the other stations, in order to compare personal equations, and while at Greenwich he exchanged time signals with the Paris observers, thus making an independent determination of that longitude through another cable.

The following is a comparison of results:

	NIGHTS.	M.	SEC.
Brest—Greenwich	6	17	57.13
Greenwich—Paris	5	9	21.11
Brest—Paris (sum)		27	18.24
Brest—Paris (direct)	9	27	18.18

showing a difference only of 0.06 seconds, which is to be equally distributed between the several values. The French determination, by telegraph, of Brest—Paris, made in 1863, is within 0.01 second the same as above, while that of Paris—Greenwich, made earlier, is 0.46 seconds less than the value now found. It is a singular combination of circumstances, which led to the correction of the longitude between the two principal observatories of Europe by American astronomers.

For the longitude Harvard-Greenwich we have now three independent results, obtained in different years, by different observers, and through different cables; for in 1870 the two cables were joined at St. Pierre; and the signals exchanged directly between Brest and Duxbury, while in 1872 an intermediate station was made at St. Pierre, whence the signals were sent, *viâ* Sydney and the provinces, to Cambridge. The results are:

LONGITUDE HARVARD OBSERVATORY FROM GREENWICH OBSERVATORY.

	H.	M.	S.		H.	M.	S
1867	4	44	31.00	1872	4	44	30.99
1870	4	44	31.05				
Mean					4	44	31.01

The close agreement of these results indicates a very near approximation to the truth, and this fundamental longitude may now be considered as settled. Adding to the above value the difference in time between the Washington and Harvard Observatories, 23 minutes 12.12 seconds, we get for Washington 5 hours 8 minutes 12.12 seconds.

DEPOSIT ON ZINC.—At a recent meeting of the Chemical Society, a paper, "On the Nature of the Black Deposit in a Copper Zinc Couple," by Dr. J. H. Gladstone, F. R. S., and A. Tribe, F. C. S., was read. As it had been suggested that the black deposit referred to contained more or less metallic zinc, the authors had instituted experiments to ascertain the truth of the matter. When the solution of copper sulphate is poured on the zinc, a deposit of pure copper is produced as long as the solution contains any of that metal. As soon, however, as the copper is exhausted, other reactions supervene : zinc oxide is formed by the action of the oxygen dissolved in the water, and metallic zinc is also deposited. Such a black deposit examined under the microscope is seen to consist of branches of crystalized copper studded with crystals of metallic zinc, the latter of which at once disappear if washed with a solution of copper sulphate. It would therefore appear that the black deposit on the copper-zinc couple as usually prepared, can contain little or no metallic zinc. After the reading of the paper, Dr. Russell said that the statement, that as long as there was excess of copper sulphate in solution no zinc was deposited along with the copper on the zinc plate, was at variance with certain experiments he had made some time ago. When a zinc plate is immersed in a dilute solution of copper sulphate, it immediately becomes covered with a black deposit; but if the plate be moved about in the liquid so as to remove it from the solution of zinc sulphate formed in contact with it, the deposit immediately acquires a red color. The black deposit, moreover, evolves hydrogen when treated with acid, whilst the red does not. Dr. Müller remarked that iron plunged into a solution of sulphate of copper gives at once a red deposit; moreover, any metal appearing black from being in a minutely divided state acquires its proper color on being rubbed with an agate burnisher, but this black deposit does not. Dr. Wright observed that, *a priori*, it was quite possible that zinc and copper should be deposited together, since brass could be electro-deposited.

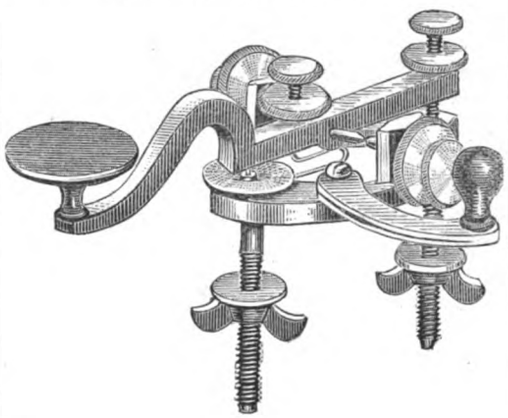
A DOGMATIC DEFINITION OF THE TELEGRAPH.—"Sam," said a darkey to his ebony brother, "how am it dat dis yaa telegraf carries de news from dem wires?" "Well Cæsar, now s'pose dar am a dog free miles long." "Nebber was such big dog; don' b'leib dat!" "You jess wait minit; I'se only illustratin', you stupid nigger. Now, dis yaa dog, you see, jess puts his front feets on de Hoboken sho', and he puts his behind feets on de New York sho'." "Yesser." "Now, s'pose you walk on dis yaa dog's tail in New York—" "Yesser." "He'll bark, won't he?" "Yesser." "Well, where will dat dog bark?" "In Hoboken, I calc'late." "Dat am jest it. You walk on de dog's tail in New York, an' he bark in Hoboken; an' dat's de way de telegraf works." "Yesser; dasso—dasso! You's right, by golly,"

RECOVERY OF THE BROKEN BRAZILIAN CABLE.

The section of the cable between Lisbon and Madeira, which was broken while being laid, has been recovered and repaired. On the 22d ult. the shore end of the line was successfully laid at Madeira, and telegraphic communication is now perfect between the two points.

The Western Union Telegraph office transmitted 80,248 words of press report during the session of the Republican State Convention in Worcester, Wednesday. Mr. Bradford, the manager of the office, is entitled to much credit for the manner in which he handled this great rush of business.—*Boston Journal*, 12*th*.

WATTS & COMPANY,



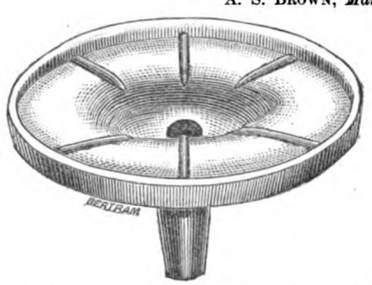
47 Holliday Street,

Baltimore, Md.,

SOLE MANUFACTURERS OF THE

PATENT CIRCUIT-CLOSER KEY,

Which has met with marked success.



Price, $5 50 plain; $7 nickel-plated.

The following is from a competent judge, written after some weeks' trial.

145 BROADWAY, NEW YORK, Sept. 22d, 1873.

DEAR SIR,—Your circuit-closing attachment on the key, left with me for trial, is pronounced by all who have used it a decided and much-needed improvement on the common form.

Respectfully,
A. S. BROWN, *Manager.*

The Best Form of Battery Insulator Offered.

SIMPLE AND PERFECT.

Made of porcelain, handsome in appearance. Occupies little more space than the cell it supports. Each cell of battery completely isolated. Leakage is reduced to the minimum by the use of it.

General Superintendent Van Horn, Southern Division W. U. Tel. Co., writes of it:

"We have now in use a thousand or fifteen hundred of your battery insulators, and expect to order many more before the close of the year.

We have never used any battery insulator that equals it in any respect. In fact, it appears to be as near perfect as we can reasonably expect, in a contrivance for that purpose."

Price 40 cents.

We offer a very excellent article of Galvanized Wire, superior to any in the market. The linemen on Baltimore and Ohio R. R. say they have never seen its equal for toughness and flexibility.

Special attention given to building.

Estimates given for any amount of material for telegraph construction or extension.

SWITCHES, GALVANOMETERS, RESISTANCE COILS, &c., to order.

Designs for Switch Boards for special service furnished.

SCOTT'S PATENT ANNUNCIATOR,

for Hotels and Residences.

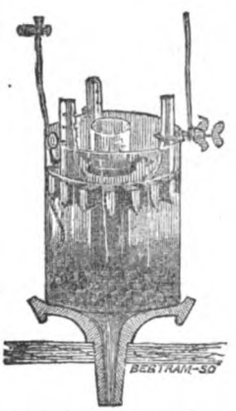
Connect with the lines of the WESTERN UNION TELEGRAPH COMPANY at Pollard, Ala.

Governed by the same Rules and Regulations as the Western Union Telegraph Company.

WATTS & COMPANY,

47 Holliday Street,



Baltimore, Md.,

MANUFACTURE

Telegraph and Electrical Instruments

OF EVERY DESCRIPTION.

Facilities for supplying any description of Machinery or Material equal to any in the United States.

Patented Dec. 31, 1872.

OVER SIX THOUSAND cells of the Baltimore Battery in use by the Gold and Stock Telegraph Company of New York in their Private Line Department, is a sufficient acknowledgement of its merit, as a form of the gravity battery, combining the valuable principles of

Economy, Cleanliness and Constancy,

"—in fact a base-burner."

F. L. POPE,
Telegrapher, July 5th, '73.

SELF-FEEDING,

No Sulphate of Copper can reach the Sulphate of Zinc Solution.

The shape of Zinc and Copper, which, with the tube, were patented December 31st, 1872, secures the largest surface with least weight of the metals. Half pound sulphate copper per month, ample supply for No. 2, or 3.

Following is one of the many letters we have from reliable telegraphers:

PIEDMONT, W. Va., September 28th, 1873.

Messrs. WATTS & Co.,
Baltimore, Md.

GENTLEMEN:—On January 1st, 1873, I put up 75 cells of your No. 2, Baltimore Battery, in place of 40 cells of carbon, from which two railroad wires of 100 miles each, are supplied. It has not since been taken down or cleaned, and has required no attention, except to fill the tubes with blue stone, once each month, and replenish the fluid once or twice during this period, made necessary by evaporation.

I am fully convinced, from long experience, that this is superior to any other form of the gravity battery.

It has now been in constant use for nine months, and will not need new zinc until after January next.

Respectfully,
J. G. NESBITT, *Manager.*

ORDERS FOR THIS BATTERY PROMPTLY FILLED.

A large stock constantly on hand.

No. 1 for Electro-motors, R. R. signals or similar service,	$2.25
No. 2 ordinary local or Printing Telegraph main	$1.75
No. 3 ordinary main	$1.25

A very Superior Main Line Sounder.

Brass, $22.50. Nickel-plated, $25.00.

For wrecking purposes or temporary offices, this instrument is without a rival.

A perfect combination, handsome, good-sounding instrument.

NO LOCAL REQUIRED.

Well seasoned black walnut box, large enough for pencils, paper, plyers and office wire, in addition to the instrument, $4. Larger size for climbers, vises, &c., $5.50.

RELAYS, SOUNDERS AND KEYS,

always on hand, plain or plated.

Our Challange Sounder is the noisest instrument made.

THE BEST TELEGRAPH MATERIAL IN THE WORLD

IS SUPPLIED BY

L. G. TILLOTSON & CO.,

8 Dey Street, New York,

MANUFACTURERS, DEALERS and IMPORTERS

OF

TELEGRAPH MACHINERY, SUPPLIES

AND

Line Equipment of every Description.

MATERIAL AND INSTRUMENTS

always on hand, for the equipment of lines of any length, at a moment's notice.

We furnish first-class goods at low prices. Liberal arrangements made with Superintendents, Contractors and Builders of Telegraph Lines.

Registers	$38 00 to $45 00
Spring Registers	47 50 .....
Relays	14 00 to 18 00
Sounders	3 50 to 7 50
Keys	4 00 to 6 50
Main Line Sounders	14 00 to 18 00
Combination Sets	20 00 to 30 00

Galvanometers, $7 00 upward.

POCKET INSTRUMENTS, Nickel Plated, in Hard Rubber Cases, 1¾x2x5 inches.

CUT-OUTS, Plug, Peg or Button, with or without Lightning Arresters, for one, two or more Lines.

JONES' PATENT LOCK SWITCHES, the best and cheapest in use, with or without Lightning Arresters.

PEG or PIN, CULGAN, REPEATING, GROUND, LOCAL, BATTERY and SINGLE BUTTON SWITCHES.

LIGHTNING ARRESTERS for any number of wires, of most approved patterns.

Electro-Magnets,
Permanent Magnets,
Apparatus for Students and Amateur Telegraphers,
Electric Motors,
Printing and Dial Instruments,
Electrical Annunciators,
Fire and Burglar Alarms,
Electro-Medical Instruments.

RHUMKORFF COILS, from ¼ to 10 inch spark.

GEISSLER'S TUBES, from $1.00 upward.

ELECTRICAL CALL AND ALARM BELLS in great variety, from $6.50 upward.

INSTRUMENTS furnished, Nickel Plated, at 20 per cent. advance on List Prices.

OFFICE WIRES, from 80c. to $1.25 per pound.

GUTTA-PERCHA COVERED WIRES, all sizes.

BISHOP'S NEW COMPOUND COVERED WIRE, for running into offices, 4c. per foot.

MAGNET WIRES, in Silk and Cotton, at Factory prices.

INSULATED WIRES for special purposes made to order.

SILK COVERED SWITCH CORD, one, two or more conductors.

PATENT MESSAGE HOOKS, the best ever introduced, prices 65c. and 75c. per dozen.

MANIFOLD PAPER and AGATE STYLUS at bottom prices.

Cables and Submarine Wires.
Repairers' Tools and Tool Bags.
Glass and Rubber Window Tubes.
Insulators of every Description.
Brackets, Pins and Spikes.

HILL, CALLAUD, GROVE, BUNSEN, CARBON, DANIELLS, LE CLANCHE, NITRO-CHROMIC, AND OTHER STYLES OF BATTERY IN ANY QUANTITIES.

PURE CHEMICALS AT LOWEST PRICES.

SULPHATE OF COPPER A SPECIALTY, AND PRICES VERY LOW.

CARBON PLATES made to order for Grenil, Smee, Stohrer and other Batteries.

OFFICE FIXTURES AND BATTERY UTENSILS OF EVERY DESCRIPTION.

"Smith's Manual of Telegraph," - - - - 30 cents.

ALL STANDARD WORKS on ELECTRICITY AND TELEGRAPHY.

SOLE AGENTS FOR

THE LECLANCHE BATTERY CO.

Offer for Sale this celebrated Battery,

(SECURED BY LETTERS PATENT,)

Of which they are the exclusive owners in this country.

Over 300,000 are now in use in Europe,

and have recently been adopted by the French Government in preference to the Calland, which had been used by them for several years.

WE RECOMMEND THEM FOR

Telegraphy (open circuit), Railroad Signals, Hotel Annunciators, Burglar Alarms, Electric Bells, Clocks, &c.

AMONG ITS NUMEROUS ADVANTAGES ARE—

ABSENCE OF ACIDS AND SALTS OF COPPER,
ITS GREAT CLEANLINESS,
WONDERFUL DURABILITY,
ECONOMY IN RUNNING EXPENSES,
ENTIRE ABSENCE OF ODOR.

This Battery will last without any attention from six months to three years.

A large number of Cups are already in use in this country on Burglar Alarms, Electric Bells, &c., and are giving entire satisfaction. The Western Union has a number of Cups put up November 26th, 1872, that are still running.

For further particulars apply to

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 22. NEW YORK, OCTOBER 15, 1873. WHOLE NO. 143.

WESTERN UNION TELEGRAPH CO.

ANNUAL MEETING.

The Annual Meeting of the Western Union Telegraph Company was held at the Company's office, 145 Broadway, New York, October 8th, on which occasion a large proportion of the capital was represented. The following report was presented by Hon. WILLIAM ORTON, President of the Company :

REPORT OF THE PRESIDENT.

To the Stockholders of the Western Union Telegraph Company :

I have the honor to submit the following report of the operations of the Company for the fiscal year ending June 30, 1873, and of the condition of its affairs on that day. The capital stock of the Company at the close of business on that day was $41,073,410, of which there was outstanding $33,778,175, and owned by the Company, $7,295,235. The debt of the Company on that day was $6,038,410, of which there was due Oct. 1, 1873, for American Telegraph Company bonds, $89,500 ; in November, 1875, for Western Union currency bonds, $4,448,900; in 1902, for Western Union gold bonds, $1,500,000.

The gross receipts of the Company for the year, from all sources, were $9,333,018.51 ; the gross expenses, $6,575,055.82 ; and the net earnings, $2,757,962.69.

This amount has been applied as follows :

Construction and purchase of new lines	$1,342,905 97
Interest on bonds	317,793 00
Real estate	62,214 40
Purchase of sundry stocks of Telegraph Companies in Western Union Company's system	41,576 69
Paid for $50,000 Western Electric Manufacturing Company's stock	39,000 00
Patents (on account of Stearns Duplex)	19,268 00
Miscellaneous	402 50
Total	$1,72 ',450 56
The balance has been carried to the credit of income account	1,035,512 13
Total	$2,757,962 69

On the 1st day of July, 1872, the Company operated 62,032 miles of line, 137,190 miles of wire, and 5,237 offices. At the close of the year ending June 30, 1873, it operated 65,757 miles of line, 154,471 miles of wire, and 5,740 offices. The increase during the year has been 3,725 miles of line, or 6 per cent.; 17,281 miles of wire, or 12.5 per cent., and 503 offices, or 9.5 per cent. For the construction, reconstruction and repair of lines, there were used 141,498 poles, 261,715 cross-arms, 1,033,270 insulators, and 1,100,265 pins and brackets. There were in the employ of the Company, on the 30th of June, 1873, 9,190 persons. Of these, four were general superintendents of divisions, 29 superintendents of districts, 5,514 managers and operators, 1,830 messengers, 661 clerks, 589 foremen of construction and repairmen, 116 mechanics in factories, 84 battery-men, and 275 miscellaneous. There were in use on the lines of the Company at that date 6,350 sets of instruments for reading by sound, 1,878 recording instrument, 8,601 relay magnets, 8,905 transmitting keys, 227 repeaters, 15 printing instruments, 94 sets of duplex instruments, 2,662 switch-boards, 3,472 cut-offs, 3,029 lightning arrestors, 21,777 cups of main battery, and 11,717 cups of local battery. The cost of new instruments and apparatus supplied during the year was $140,877.52, and of battery material and supplies, $146,793.68.

The number of messages transmitted during the year ending June 30, 1872, was 12,444,499, and for the year ending June 30, 1873, 14,456,832, being an increase of 2,012,333, or 16.1 per cent. This includes press reports reduced to messages on the basis of 30 words to each message. The average toll collected upon each message for the last year was 61 cents, the average cost of transmission 42 cents, and the average profit per message 19 cents.

REPAIRS AND RECONSTRUCTION.

During the past year, $706,789.58 were expended for repairs of line, and $632,753 for reconstruction, making a total expenditure for maintenance of line of $1,339,542.58, an increase over the previous year of $409,537.41, or 44 per cent. The increase during the past year in the cost of maintenance of line is mainly for reconstruction, the cost of which was $354,213.28 in excess of the previous year. This increase is principally confined to the Eastern and Western States, and much of it is of an exceptional character, and I hope not likely to recur. Severe storms have prevailed, particularly in January and March, causing great injury to the lines and necessitating large outlays for repairs. Great expense has also been incurred in the removal of lines to accommodate railroad extensions, additions of tracks and sidings, and the removal and erection of buildings, principally on the Pennsylvania Central, New York Central, and Lake Shore railroads, and to a considerable extent on many other railroads in the Eastern and Western States. The annual cost of maintenance of the plant for the past five years has been as follows : Cost of maintenance per mile of line—1869, $14.50 ; 1870, $15.30 ; 1871, $15 ; 1872, $16.59 ; 1873, $20.37. Cost of maintenance per mile of wire—1869, $7.23 ; 1870, $7.72 ; 1871, $7.23 ; 1872, $7.67 ; 1873, $8.66. The cost of reconstruction was heavier than usual in the Eastern States, on account of the large number of poles which required renewal during the past year.

The maintenance of the plant in the best possible state of efficiency is a necessity which will be readily appreciated, as the capacity of the wires for the transmission of messages, and consequently for earning money, depends upon their condition for work in all weather. While every effort has been made to keep the cost of maintenance down to the lowest practicable limit, the average cost per mile has not materially changed during the past five years, and it is not likely that the annual expense will be materially less per mile for the next few years.

Great pains have been taken, during the past seven years, to secure a better and more durable kind of timber for the poles than was formerly used, and it is hoped that the cost of reconstruction will hereafter be somewhat decreased.

In Europe a cheaper class of timber is employed for poles, which are treated with sulphate of copper or creosote to make them more enduring, but investigation shows that the duration of the treated poles in Europe is no greater than that of our best natural timber. The lines which we are now reconstructing were built before the consolidation, and are inferior to those which we are now building, and when reconstructed they are better than when originally built.

It has been the policy of the Company, under its present management, in the direction of repairs and reconstruction, not merely to effect such repairs as would enable the lines to be worked, but to put them in better condition than they had been in before, keeping always in view the inevitable growth of the business, and the constant necessity for providing additional facilities. To illustrate : A line of poles bearing three wires require renewal; they are replaced by poles capable of bearing a dozen wires, and which will last twice as long as the old ones. If only the three wires are placed upon these poles, the whole outlay is charged to profit and loss, although the value of the renewed line is much greater than that of the one replaced when the latter was new. As additional wires are put up on such poles, the cost, merely, of such additions is charged to construction. Under this policy the whole property of the Company is improved every year more than that year's portion of natural decay ; so that the apprehension, sometimes expressed, of what appears to be the natural result of annual deterioration of the Company's property is groundless. The average condition of the whole property is better at the end of every year than at the beginning.

MONEY TRANSFER SERVICE.

On the first of July the transfer system had been in operation 21 months, with very satisfactory results. The increase of the business has been greatly beyond the expectation of its results when established. The revenue of the Company from this source for the first nine months was $8,936 ; for the same nine months, one year later, it was $45,811, an increase of more than five-fold. The revenue from this service, during the past year, was $58,000 ; the number of trasfers, 20,000 ; the amount transferred, $1,602,000. The average amount of each transfer was about $80. Ninety-two new money order offices have been opened during the year. The service has increased in promptitude and efficiency, and measures are now in progress which, it is expected, will still further improve it. Judging of the future by the past, it is not easy to estimate the growth of this business, or to appreciate the results which it may ultimately reach. If the same rate of increase is

Digitized by Google

maintained during the present year that has been developed during the past twelve months, our monthly revenue from transfers will be over $8,000, or at the rate of $100,000 per annum. It is a gratifying and healthy feature of the business, that while the number of transfers is increasing rapidly, the average amount transferred is diminishing; for, as the average amount of transfers grows smaller, the risk of loss diminishes, and the profits of the business are proportionately greater. Experience seems to prove that our transfer system is the best that can be devised. The alterations in the details that have been found advisable since its inauguration have been few and unimportant, while an enlarged knowledge of the business, and familiarity with its working, seems to indicate the necessity only of a rigid adherence to all the regulations established in order to make its operation a complete success.

FREE MESSAGES.

The free messages, so classified in our accounts, transmitted by the Company during the past year, amount, at regular toll, to $766,000. Of this sum, $565,000, or 72 per cent., was performed for railroad and other transportation companies, all of which render us similar service in return. Without this service our lines could not be kept up so cheaply, nor our business so well conducted. Such messages are not free business in the proper sense of the term. They are sent under contracts which stipulate to give the Company an equivalent in right of way, transportation of men and material, and labor to maintain and operate our lines. While the contracts vary in terms they are in the aggregate very favorable to this Company. Of the balance of the free service, $83,000 worth is performed for the directors, officers and operators of the Company; $22,000 on account of rent; $18,000 for connecting telegraph companies; $58,000 for complimentary, and $20,000 for miscellaneous messages. The $83,000 of Western Union business includes the telegraphic correspondence of all the officers and agents of the Company. It has been the constant effort of the management to curtail this business, and the figures now reached are believed to be low and reasonable. The rent account explains itself. The items thus charged are generally limited to a specific sum per month, and the total business is constantly and carefully scrutinized. Instead of paying in cash we pay in telegraphing, and the telegraphing, as a rule, pays more rent than the same amount in money. The items of railroad transportation, telegraph, and rent messages, amount in the aggregate to nearly $700,000, or 90 per cent. of the whole free business.

THE TARIFFS.

During the past year two important modifications have been made in the tariffs. The first change was the abrogation of all Western Union rates bove $2.50, which took effect Feb. 1. The second important change was the extension of the square rate over the territory west of Omaha and east of Utah, and the equalization of the rates in the Eastern, Central and Southern States, which took effect July 1, 1873. The rates previous to July, 1873, were about 23 per cent. higher in the Western, and 40 per cent. higher in the Southern than in the Eastern States. This inequality was the subject of complaint in the Western and Southern States, and formed one of the strongest arguments in favor of the extension of competing lines and of governmental interference. Another serious objection to these unequal rates was that the special rates between competing points were so low in comparison that messages for distant points in the West or South could be sent to certain central points over our lines at special rates, and then be forwarded at local rates to their destination, at a considerable reduction from the through rate. For example: The square rate to offices in the vicinity of Chicago was $2. The special rate between New York and Chicago was $1, and, as the local rate from Chicago was only 40 cents, our customers or the opposition lines could send messages for such points to Chicago, and deliver them by our own lines, at a reduction of 50 to 60 cents from our through rates. This condition of things existed throughout the South and West, and to some extent in the East, and could only be remedied by an equalization of the rates, such as has been recently inaugurated.

EARNINGS IN SEVEN YEARS.

The following statement shows the net earnings of the Company since the consolidation, in 1866, and the disposition which has been made thereof:

The surplus of Income Account, July 1, 1866, was	$275,357 24
The net profits for seven years, from July 1, 1866, to June 30, 1873, have been	20,312,618 81
Making an aggregate, June 30, 1873, of	$20,587,976 05
Of this sum there has been	
Distributed in dividends to stockholders	4,857,239 34
Disbursed for interest on the Company's bonds	2,216,194 98
The balance	$13,514,541 73
is represented as follows:	
Construction of new lines and the erection of additional wires	$4,405,180 44
Purchase of telegraph lines and of the stock of companies controlled by the Western Union Company, on which or dividends are paid as rental	695,428 95
Western Union stock (72,952 shares)	4,054,483 07
Gold and Stock Telegraph Company's stock (47,710 shares)	1,173,509 00
International Ocean Telegraph Company's stock (10,384 shares)	961,556 42
Pacific and Atlantic Telegraph Company's stock (49,917 shares)	510,274 50
Anglo-American Telegraph Company's stock (£1,308 0s. 0d.)	10,000 00
Western Electric Mfg. Co.'s stock (500 shares)	39,000 00
Western Union Bonds redeemed and canceled	974,075 00
Western Union Broadway and Dey street Mortgage Sinking Fund	30,000 00
Real estate (exclusive of Broadway and Dey street property)	318,263 14
Patent—The Page and Duplex Telegraph	73,758 00
Cable steamer	12,665 19
Western Union Bonds not canceled ($7,500)	6,750 00
Fraction of share (old issue) redeemed and canceled	42 50
Total	$13,264,986 21
Leaving an excess of	$249,555 52

which excess is applicable on account of Sinking Fund appropriations not yet used for redemption of bonds.

All the above items are entered at the actual cost to the Company, in cash, except the $1,173,509 in stock of the Gold and Stock Telegraph Company, which is stated at par, and we should not be willing to sell it at that rate. Many of the other items are worth much more than cost.

THE INTERNATIONAL OCEAN TELEGRAPH COMPANY.

During the past year the Western Union Company have acquired control of the International Ocean Telegraph Company, whose lines extend from Lake City, Fla., to Havana, Cuba. The capital stock of this Company is $1,500,000, of which $850,000 is in common, and $650,000 preferred, stock. The Western Union Company purchased of the common stock $538,500, and of the preferred stock $499,900, making a total of $1,038,400 at the par value. The actual cost to us was $961,556.42. The International Ocean Company possess a fifty years' exclusive grant from the Spanish Government to lay and operate cables between Cuba and the United States, and a fifteen years' exclusive grant from the Government of the United States to lay and operate cables between the coast of Florida and the West India Islands. When the controlling interest in the stock of this Company was purchased, communication by cable between Florida and Havana was interrupted. In April last one of the cables between Key West and Havana was repaired, and a new one also laid down, and both are now in good working order. The lines of the International Ocean Company are now doing a good and profitable business with Cuba, Porto Rico and Jamaica, and when the cables connecting Jamaica with the other West India Islands, and to Central and South America, are completed, which, it is confidently expected, will be in a short time, the traffic upon these lines, which constitute the only outlet for the telegraphic correspondence of these countries with the United States and Europe, will become very large and important. The net profit of the International Ocean Company is now at the rate of about $200,000 per annum.

PACIFIC AND ATLANTIC.

We have also acquired during the last year a majority of the stock of the Pacific and Atlantic Telegraph Company, and negotiations have been in progress for some time with a view to leasing their lines. The capital of that Company is $2,000,000, Their lines extend from New York via Philadelphia and Baltimore to Pittsburg, Columbus, Indianapolis, St. Louis and St. Paul, branching at Dubuque to Chicago, and from Chicago to Cincinnati, Louisville, Nashville, Memphis and New Orleans. They own about 5,000 miles of line and 10,000 miles of wire, and the gross receipts last year were about $500,000. It is believed that an arrangement will be made, satisfactory to the holders of the balance of the stock, by which the lines will be turned over to the Western Union Company at an early day.

PNEUMATIC TUBES AND SUBTERRANEAN LINES.

In February last the Executive Committee authorized me to send Mr. George B. Prescott, the Electrician of the Company, and Gen. Thomas T. Eckert, the General Superintendent of the Eastern Division, to Europe, for the purpose of making a careful inspection of the system of pneumatic tubes and subterranean telegraph lines now in operation in the principal cities, and also to examine the working of the telegraph lines generally. They found the most complete system of pneumatic tubes and subterrean lines in operation in London, although both systems were extensively employed in Paris, Berlin, and other cities. In London about 13 miles of pneumatic tubing have been laid down, at a cost of £16,000, and about 10,000 messages per day are sent through them. The average time occupied in the transmission of messages through the pneumatic tubes is about two minutes, and the number of messages transmitted in each carrier is from eight to twenty, according to the size of the tubes. There are thirteen stations in the City of London connected by pneumatic tubes; and it is the opinion of Mr. Scudamore, the Manager of the English telegraphs, that it would be impossible to properly transmit the

Digitized by Google

large number of messages between these offices in any other way than by pneumatic tubes. The system of underground lines in England embraces 3,000 miles of wires and nearly 100 miles of iron piping. There are, upon an average, 60 wires in each pipe, and the average cost per mile of wire is £23. While the first cost of underground lines is considerably greater than for those on poles, the interruption in the working of them and the cost of maintenance are claimed to be less, and the system is favorably regarded for the large cities. Messrs. Prescott and Eckert obtained minute and accurate information as to the best methods of constructing pneumatic tubes and underground lines, as well as much other valuable information in relation to the working of the telegraphs generally, which will be found of great importance in the future operation of our lines.

When our new building on the corner of Dey street and Broadway is completed, it is proposed to connect it by pneumatic tubes with the Stock and Produce Exchanges, and other important branch offices in the city. It is also contemplated to lay down subterranean lines in the lower part of the city, with the view of testing their efficiency and economy as compared with the present mode of construction.

STEARNS' DUPLEX TELEGRAPH.

The purchase of the patents for the United States and Canada of this most important and valuable of all the improvements which have been made since the Morse telegraph was first established, was mentioned in my last Annual Report. During the past year we have largely increased the number of Duplex instruments and apparatus, by means of which messages can be transmitted in opposite directions upon a single wire at the same time. We have now in operation over 100 sets, and it is the intention to have all our principal stations completely equipped with them as soon as they can be supplied from the factory. We are now operating more than 150,000 miles of wire, and during the past two years have been extending at the rate of nearly 20,000 miles of wire per annum. The Duplex apparatus is capable of doubling the capacity of these wires at a comparatively small cost. The value of this increase of facilities can be approximately ascertained by estimating the saving in the investment for wire and the annual saving in repairs and maintenance of additional wires. But the great value of the Duplex does not consist in the saving in the investment in wires and the cost of repairs and maintenance, but in its ability to double the capacity of a wire when we have but one, and when no amount of money previously invested in wires, or even possible to be expended in repairs, can provide another. Sometimes a storm or conflagration causes the interruption of all the wires on an important route at a time when every wire is needed to keep business moving. Communication is restored upon one wire at a time, and it is then that the great value of the Duplex becomes apparent. With it the moment one wire is restored we have two, and when we have a second we have four, and so on.

During the extraordinary excitement of the past three weeks our wires between the principal cities have been taxed to their utmost capacity, and if we had double the number on some routes they would have been insufficient. Every set of Duplex has been brought into requisition, and only our inability to procure them has prevented the use of a larger number. A minor consideration, and yet important one, is the fact that the Duplex can be substituted for, and its use does not involve the duplication of, the ordinary apparatus. It works equally well double or single. As our operators acquire experience in its use, the difficulties which attended it at first wholly disappear. They now adjust with such facility that the change from single to double is made in less than a minute, and I confidently expect that, by the time the necessary instruments can be manufactured, they will be largely introduced on railroad and other way wires.

GOLD AND STOCK TELEGRAPH COMPANY.

The Western Union Company own 47,710 shares, of the par value of $25 per share, of the stock of the Gold and Stock Telegraph Company, out of the capital of 100,000 shares. The Gold and Stock Telegraph Company transmits its reports over the Western Union lines, and during the past year paid us in tolls $77,995, and one dividend of 3 per cent. amounting to $35,970. Within the last two years the Gold and Stock Telegraph Company have added to their property, in instruments, poles, wires, fixtures, &c., about $400,000. The gross receipts of that Company in 1871 were $236,215; in 1872, $534,780, and in 1873, $623,900. They had earning revenue:

In 1869... 572 instruments	In 1872....1,594 instruments.
In 1870 ... 741 instruments.	In 1873....1,783 instruments.
In 1871.... 830 instruments.	

The Private Line department in the City of New York has a rental of $49,290 per annum, and is steadily increasing. The net income of the Company from private lines in other cities is equal to that of this city, and is also increasing steadily.

In order to be prepared for the large increase of business, the expenditure for construction has been very large, and has interfered with the payment of regular dividends, but the Company is now becoming well supplied with lines and equipments, and it is confidently anticipated that regular dividends will be paid hereafter.

THE COMPANY'S FACTORY.

In January last the factory in New Church street was completed at a cost of $139,772, of which $85,000 was paid for the land and building. The lot is 104 feet on New Church street, by an average depth of 36 feet. The building is admirably adapted to the manufacture of telegraph apparatus, and is in close proximity to the permanent headquarters of the Company in their new building. The factory is now capable of supplying all the apparatus required by the Company, and its capacity can be more than doubled when required. The operations of the factory for the past six months show a small profit after deducting the interest on the investment. The apparatus made at this factory greatly excels any other manufactured in this country, and it is the superior quality of the material and workmanship, rather than the saving in the cost of the instruments, which constituted the great inducement for establishing it.

THE NEW BUILDING.

The avails of the $1,500,000 of bonds issued on the mortgage of the real estate at the corner of Broadway and Dey street amounted to		$1,497,883 69
Accrued interest received		15,106 34
Interest on avails unexpended July 1, 1873		30,075 00
Received for sale of old material		1,000 00
Total received up to July 1, 1873		$1,544,065 03
Expenditures for purchase of the real estate at the corner of Broadway and Dey street up to July 1, 1873		855,000 00
Interest on bonds	$121,012 50	
Taxes, &c., &c	10,869 56	
Interest on Dodge contract	3,320 76	
Commission on sale and expense of preparing bonds	14,720 84	
Amount paid to architect and builders	220,048 04	369,981 70
Total expended to July 1, 1873		$1,224,981 70

The work on the building has not progressed as rapidly as was expected, and it will be impossible to occupy it, as originally contemplated, in the Spring of 1874. The delay has been occasioned wholly by the inability to procure the granite within the time required. Some changes have been made in the original plan, by which the cost will be somewhat increased. All the work is being done in the most thorough and substantial manner, and the building promises to be, when completed, one of the finest in the city. The total cost for land and building, furnished and equipped with the machinery and apparatus required by the Company, will be about $1,700,000. The basement and cellar will be occupied by the Company. The first, second, and at least one other story, will be offered for rent. It is not expected that the annual cost to the Company in excess of the income from rents will be much, if any, greater in the new building than has been paid for the premises now occupied, while we shall have double the space, and superior accommodations in every particular.

At the date of the consolidation with the American Telegraph Company, July 1, 1866, the capital of the Western Union Company issued and liable to be issued was, as it now is, $41,073,410. The Company was then in possession of about 75,000 miles of wire, on which were transmitted during the year following about 5,800,000 messages. At that time all the lines on the Pacific Coast, and nearly all in the States of Iowa, Illinois, and in Northern Missouri, although working in connection with ours, were owned and controlled by other companies. Although the Western Union Company owned a line between the Missouri River and Salt Lake City, at which point connection was had with the California and Pacific Coast lines, its business from Chicago to the Missouri River was obliged to pass over the lines of another company. Since that time we have acquired, by lease and purchase, the lines of the Illinois and Mississippi Company which occupied the States of Illinois and Iowa; of the Chicago and Mississippi Company, which occupied Northern Missouri; and of the California State Company, which occupied the territory on the Pacific Coast and west of Salt Lake City.

On the 1st of July, 1873, the Western Union Company controlled and operated more than 150,000 miles of wire, and owned the controlling interest in companies operating over 10,000 miles more.

During this period of seven years, in which the Company's lines and wires have been doubled in extent, and the capital stock outstanding has been reduced by more than $7,000,000, and other property acquired representing in the aggregate more than $13,000,000, the volume of business has increased from less than 6,000,000 messages in 1866 to about 14,500,000 in 1873. The gross receipts during the same period have grown from $6,500,000 to $9,333,000, but the profits have not increased either in proportion to the volume of business or to the gross receipts, the excess of 1873 over 1866-7 being but about $130,000. A brief statement of the causes which have produced this result seems proper at this time. They are mainly these:

1. The enhanced cost of labor, of poles, wire, and all material used in constructing, maintaining and operating the lines.

2. The reduction of rates rendered necessary by the action of competing companies between stations on the route of their lines, in the first instance; and later reduction in other sections in order to equalize rates, and thereby remove the inducement for competing lines to extend still further.

No public business of equal importance is so sensitive to competition as that of the telegraph, and with no other can competition be inaugurated by the

outlay relatively of so small an amount of capital. Two classes of persons are always interested in promoting telegraphic competition—first, those who organize the companies, and hope to profit by contracts for construction of the lines, or by stock bonuses and commissions on the sales of stock ; and, second, the senders of messages, who are willing to risk the income from a moderate investment if thereby a larger sum can be saved annually from the reduction of telegraph tolls which a competing line is expected to secure.

In 1866, the only telegraph lines in the country competing with the Western Union were those of two companies—one extending from Boston to Washington, and the other from New York to Washington. The latter, let me remark, after sinking its capital of about $750,000, was sold for debts contracted, amounting to $120,000 more, and afterward leased by the purchaser to the Western Union for six per cent. per annum on that sum. But in 1867 and 1868 several new companies were organized, and the work of constructing competing lines was pushed with much earnestness during the next three years. Parties willing to subscribe liberally to the capital stock of these companies were readily found, some influenced by the promise of ten per cent. annual dividends on the par of shares for which they were asked to pay but forty per cent., and that in quarterly instalments, and others by the argument that, at the reduced rates promised, a handsome profit would result from the saving on their own messages, even if no dividends were paid on the capital. The effect of this competition upon the Western Union Company's business may be readily seen by an inspection of the results of 1870, as compared with 1869. For the latter year the gross receipts were about $7,300,000, and the net profits $2,750,000, while for 1870, although the gross receipts were nearly the same, the profits were less than the previous year by more than $500,000, and it was not until 1872 that our profits exceeded those of 1869, and then by only $40,000.

At the same time that competition has been operating to reduce the rates and increase the expenses, we have been called upon at every session of Congress, for the last four years, to defend the policy and management of the Company from charges made by members of both Houses of Congress, by officials of the Government, and in a few instances by the press. The effect of these hostile proceedings against the Company has been to induce the Executive Committee to proceed more rapidly with the work of increasing the facilities and reducing the rates than the actual condition of the Company's affairs may, at first sight, seem to justify. But little reflection will, however, be necessary in order to satisfy you of the wisdom of their action.

The scale of rates fixed by competition on the most important routes, and between the principal cities, has been applied recently to the whole country east of the Rocky Mountains, so that the inducement to subscribe capital for the extension of competing lines, in order to secure the benefit of competing rates, no longer exists. At the rates now established it is impossible for any competing company to realize profits, and some of them are known to be, and all are believed to be, operating at a loss. As a result, the extension of competing lines has ceased, and it is not believed that capital can be found wherewith to inaugurate new enterprises in any quarter. The time is not distant, therefore, when the Western Union Company will be without a substantial competitor in the conduct of a business which, notwithstanding the enormous growth of the last seven years, is still in its infancy. With the increase of wires, already provided and now in progress, the capacity of which the Duplex Apparatus, hereinbefore spoken of, will be able to double at small cost, it is believed that the constantly increasing volume of business, the growth of which will be stimulated by the present low and uniform rates, can be successfully handled with a less annual investment in new construction than has heretofore been necessary ; so that, with competition checked and in process of being extinguished, the percentage of expenses may be reduced, and the patience of the stockholders be rewarded at an early day by the resumption of regular dividends.

Respectfully submitted,
WILLIAM ORTON, *President.*

At the annual meeting of the stockholders of the Western Union Telegraph Company, held at the office of the Company, 145 Broadway, New York, October 8th, 1873, the following persons were elected Directors and Inspectors of Election for the ensuing year :

Directors.

WILLIAM ORTON,	JAMES H. BANKER,
ALONZO B. CORNELL,	HARRISON DURKEE,
NORVIN GREEN,	JOSEPH HARKER,
EDWIN D. MORGAN.	AUGUSTUS SCHELL,
W. K. THORNE,	C. VANDERBILT,
FRANK WORK,	CHESTER W. CHAPIN,
EZRA CORNELL,	CYRUS W. FIELD,
WILSON G. HUNT,	DAVID JONES,
C. LIVINGSTON,	GEORGE H. MUMFORD,
O. H. PALMER,	GEORGE M. PULLMAN,
E. S. SANFORD,	HIRAM SIBLEY,
JOHN STEWARD,	MOSES TAYLOR,
W. H. VANDERBILT,	W. R. VERMILYE,
E. B. WESLEY,	STILLMAN WITT,

E. D. WORCESTER.

Inspectors of Election.

GEO. B. PRESCOTT, LEONARD COX,
WM. ARNOUX.

WESTERN UNION TELEGRAPH COMPANY,
OFFICE OF THE GENL. SUPT. OF THE PACIFIC DIVISION,
SAN FRANCISCO, Oct. 1st, 1873.

To the Editor Journal of the Telegraph :

DEAR SIR : The following appointments, resignations and transfers have taken place since last report :

APPOINTMENTS.

F. W. A. Crain, Eugene City, Oregon.
A. L. Smith, Hollister, Cal.
C. D. Ellis, Stockton, Cal.
L. T. Cummings, Peters, Cal.
A. D. Ayres, Mineral Hill, Nevada.
M. Bounds, Woodlawn, Cal.
M. Soper, San Bernardino, Cal.
H. S. Stevens, Oregon City, Oregon.
W. McRavey, Winnemucca, Nevada.
Chas. Lagrave, Unionville, Nevada.

TRANSFERS.

G. R. Stanton, Stockton, Cal., to Reno, Nevada.
David Crawford, San Francisco, Cal., to Reno, Nevada.
G. A. Taylor, Oregon City, Oregon, to Oakland, Oregon.

RESIGNATIONS.

A. V. Peters, Eugene City, Oregon.
J. T. Prentice, Peters, Cal.
W. A. Langborne, Mineral Hill, Nevada.
C. W. Gearhart, Woodland, Cal.
T. F. Donelin, Winnemucca, Nevada.
Miss Banks, Unionville, Nevada.

Yours truly,
JAS. GAMBLE, *Genl. Supt.*

MATHEMATICS FOR NON-MATHEMATICIANS.

By WILLIAM PAGET HIGGS, LL.D., D. Sc.

DIVISION I.—THE ALGEBRA OF CONSTANT QUANTITIES.

Common Uses of Common Logarithms.

There are, of course, many important applications of logarithms that could not be included here. Some of these applications require a technical knowledge of the science to which they are applied ; others again call for a knowledge of the higher mathematics to which we have not yet attained. But perhaps the property of logarithms most interesting to the general reader is that relating to compound interest. On this point no one is so clear as the late Professor De Morgan ; and, not to make a vain attempt to embody his meaning in words as concise, it will be better to quote in full what he says. The quotation is from the "Essay on Probabilities,* p. 13.

The principle upon which mathematical abbreviation frequently proceeds is this : that where the calculation of a few results materially aids the production of a great many more, it is advisable to calculate a multitude of results, to arrange them in convenient tables of reference, and to publish them ; so that by means of one person taking a little more trouble than would otherwise fall to his share, all others may be saved labor altogether. Mathematical tables are frequently nothing but the result of labor performed once for all; but it also sometimes happens that the principle on which the labor is performed can be exemplified by a familiar case of it. We shall take that of logarithms as an instance.

Every table of logarithms is an extensive table of compound interest.—Not to embarrass ourselves with fractions, let us take a table of *cent* per *cent* compound interest. We have then the following amounts of £1 in 1, 2, 3, &c., years :

Years.	*Amount.*	*Years.*	*Amount.*
0	£1	14	£16,384
1	2	15	32,768
2	4	16	65,536
3	8	17	131,072
4	16	18	262,144
5	32	19	524,288
6	64	20	1,048,576
7	128	21	2,097,152
8	256	22	4,194,304
9	512	23	8,388,608
10	1,024	24	16,777,216
11	2,048	25	33,554,432
12	4,096	26	67,108,804
13	8,192	27	134,217,728

The property of this table is, that if we wish to multiply together any two numbers called amounts, we have only to add together the number of years they belong to, and look opposite the sum in the table of years. Thus, 11 and 12 *added* together give 23 ; 2,048 and 4,096 *multiplied* together give 8,388,608. The reason is as follows : If £1 in 11 years yield £2,048, and if this £2,048 be put out for 12 years more, then, since £1 in 12 years yields £4,096, 2,048 times as much will yield £2,048 × 4,096 ; or the amount in 11 + 12 years is the product of the amounts in 11 and 12 years. The only reason why the preceding table is not in the common sense of the word a table of logarithms, is, that its construction leaves

* "An Essay on Probabilities, and on their Application to Life Contingencies and Insurance Offices." By Augustus De Morgan, Professor of Mathematics in University College, London. Longmans & Co.

Digitized by Google

out most of the numbers. We can deal with 2,048 and 4,096, but there is nothing between them. The remedy is to construct a table of compound interest, at such an excessively small interest, that a year shall never add so much as a pound throughout. Certain considerations, by which the table may be shortened, but with which we have here nothing to do, make it convenient to suppose such a rate of interest, that £1 shall increase to £10 in not less than 100,000 years, at compound interest. Or we may suppose interest payable 100,000 times a year, and say, let the whole *yearly* interest be 1,000 per cent. per annum. Taking the first supposition, we have a part of a table of logarithms as follows:

Amount.	*Years.*	*Amount.*	*Years.*
1000	300,043	5232	371,867
1001	300,087	5233	371,875
1002	300,130	5234	371,833
1063	300,173	5235	371,892
&c.,	&c.,	&c.,	&c.

This is the light in which a common reader may view a table of logarithms. Let 1 increase to 10 at compound interest in 100,000 equal moments, then 1 will become 5,234 in 371,883 such moments; and so on. We can thus manage to put down every number, within certain limits, as an amount; and thus, within those limits, we reduce all questions of multiplication and division to addition and subtraction by reference to the tables. We thus perceive a simple principle applied with much labor, but such as is performed once for all. The notion above elucidated was the first on which logarithms were constructed; in time came more easy methods.

Professor De Morgan then recurs to another method of abbreviation, and we may, for the method will presently be very useful, continue the quotation. The abbreviation is applied to the multiplication of all the successive numbers from 1 up to some higher number.

Let [10], for instance, represent the product of all the numbers, from 1 up to 10, both inclusive, or let [10] stand for—

$$1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8 \times 9 \times 10 = 3{,}628{,}800.$$

[1] is 1; [2] is 2; [3] is 6; [4] is 24; [5] is 120; [6] is 720; [7] is 5,040; [8] 40,320; and so on. This labor becomes absolutely unbearable when the numbers become larger; thus [30] (or the numbers up to 30 multiplied together) contains 33 places of figures, and [1,000] contains 2,568 figures. But, nevertheless, we cannot deal with problems in which there are 1,000 possible cases without knowing, *either nearly or exactly*, the value of [1,000]. It will, however, be sufficient to know this value nearly; within, say, a thousandth part of the whole; that is, as nearly as when, the answer of a problem being 1,000, we find something between 999 and 1,001. We now put before the reader who can use logarithms a rule for this approximation, with an example; intending thereby to show the reader who does not comprehend the process, how mathematics enter into the abbreviation of tedious computations.

Rule.—To find very nearly the value of [a given number], from the logarithm of that number, subtract 0·4342945,* and multiply the difference by the given number, for a first step. Again, to the logarithm of the given number, add 0.7981799, and take half the sum, for a second step. Add together the results of the first and second steps, and the sum is nearly the logarithm of the product of all numbers up to the given number inclusive. For still greater exactness, add to the final result its aliquot part, whose divisor is 12 times the given number.

Example.—What is—

[30] or $1 \times 2 \times 3 \times \ldots\ldots \times 29 \times 30$?

First Step.

log. 30 = 1·4771213
0·4342945
1·0428268
30
31·284804 Result.

Second Step.

log. 30 = 1·4771213
0·7981799
2)2·2753012
1·1376506 Result.

The sum of the results is—

32·422455

which is the log. of result of problem.

The result has, therefore, 33 places of figures, of which the first six are (nearly) 264,518; or, if this be increased by its 360th (12 times 30) part, or about 735, the result is 265,253, followed by 27 ciphers, and the error is not so much of the whole as one part out of 500,000. In this way, we are able to do with more than sufficient nearness, and in a few minutes, what it would take days to arrive at by the common method and with much greater risk of error.

If we wish to find the product of all the numbers, say, from 31 to 100, both inclusive, we find [100] and [30] approximately, and divide the first by the second.

This selection from a work that should be better known to the reader of mathematical tendency will serve to illustrate the application of logarithms to extremely lengthy calculations. Another application now to be considered is to the immediate computation of amounts at compound interest, a class of calculation in which logarithms are of high value.

Before the subject can come within easy grasp, there will be necessary some explanation of other terms than those already made known. An amount at compound interest increases in what is named geometrical progression.

Arithmetical and Geometrical Progression.

An amount (a) is ordinarily understood to be capable of increase by one of two methods:

(1). It may increase by a constant difference d, as—

$$a,\ a+d,\ a+d+d,\ a+d+d+d,\ \&c.,$$

or—

$$a,\ a+d,\ a+2d,\ a+3d,\ \&c.,$$

when the progression is said to be *arithmetical*. For example—

1, 2, 3, &c.,

is an arithmetical progression, the difference, d, being 1. This progression might be written:

1, 1+1, 1+1+1, &c.

It will be seen that the last term (l) can be obtained from the formula—

$$l = a + (n-1)d,$$

where n is the number of terms, a the first term, and d the common difference. Thus—to give a self-evident example—the last term of the arithmetical series,

1, 2, 3, 4, 5,

is—

$$1 + (5-1)1 = 5.$$

(2). Or an amount may increase by multiplication by a constant quantity. An amount is then said to increase in *geometrical* progression, as

2, 4, 8, 16, 32, &c.

While, in any *arithmetical* series or progression, a number or term subtracted from the next following number or term, yields a constant *difference;* in a *geometrical* series, a term divided into the next term gives a constant *quotient* or *ratio.* The common ratio of the series just given is 2. The general algebraic formula for the geometrical series is—

$$a,\ a\,r,\ (a\,r)r,\ (a\,r\,r)r,\ \&c.,$$

or—

$$a,\ a\,r,\ a\,r^2,\ a\,r^3,\ \&c.,$$

a being the first term, and r the common ratio or constant multiplier. Study of the series will show us that the last term (l) will be equal to

$$l = a\,r^{n-1}.$$

The last term in the given series is thus—

$$l = 2(2^{5-1}) = 2(2^4) = 2 \times 16 = 32.$$

An amount increasing at compound interest or in geometrical progression, is thus put before us in a new light. For, if it be required to know—what will be the amount of a given sum placed at compound interest for so many years, at such a rate per cent.—we can put the question under the form—what is the last term (the amount) of a geometrical series, to be obtained from a knowledge of the first term (the sum placed out), the number of terms (years), and the common ratio (rate per cent).

Example.—Required the amount, at compound interest, of £2,273, in 3 years, at 5 per cent?

Here 2,273 is the first term; 3 the number of terms; and 1·05 (the amount of £1 for 1 year) the common ratio. Now, the formula $l = a\,r^{n-1}$ directs us to raise r, the common ratio, to the n' power, and to multiply the result by the first term. The log. of $r = 1{\cdot}05$ is 0·0211893, and this multiplied by n or 3 (see Rule III. for logarithms) is = 0·0635679.

log. (1.05 × = 0·0635679
log. 2 ,3 = 3·3565994
3·4201673 log. 2631.2.

Answer £2,631 10s.

Had we from the amount of £2,631 10s. sought the principal, the interest being given, the following process—the reverse of the preceding—would have been adopted:

$2631{\cdot}2 \div 1{\cdot}05^3$ = principal, or—

$$\frac{l}{r^n} = a.$$

log. 2631·2 = 34201673
log. $1{\cdot}05^3$ = 0·0635679
3·3565994 = log 2273.

Had the rate of interest been demanded, the method employed would obviously have been that indicated by the expression—

$1{\cdot}05^1 = 2631{\cdot}2 \div 2273$, since

$$r^n = \frac{l}{a}.$$

$2273 \times 1{\cdot}05^3 = 261{\cdot}2$; or
log. 2631·2 = 3·4201673
log. 2273 = 3·3565994
3)0·0635670
0·0211893 = log. 1·05.

1·05 is an increment to 1 of 0·05, or 5 in the hundred (per centum).

Had the time been required, we find—

log. $1{\cdot}05^3$ ÷ log. 1·05 = 3, the number of years; or—

$$\frac{r^n}{r} = n.$$

A very neat application of the laws of compound interest to electrical science will be found in the appendix to Mr. Culley's "Handbook of the Telegraph," in the determination of the state of insulation of a cable by fall of charge.

* These numbers are obtained by calculation, which need not be given here.

TELEGRAPHERS' MUTUAL LIFE INSURANCE ASSOCIATION.

ACKNOWLEDGMENT OF RECEIPTS FOR ASSESSMENTS NOS. 47 AND 48, UP TO OCTOBER 11.

4, 8, 13, 15, 17, 21, 22, 23, 26, 27, 29, 31, 33, 39, 46, 55, 59, 61, 67, 70, 72, 75, 76, 77, 80, 82, 89, 90, 95, 97, 99, 100, 101, 107, 108, 111, 114, 120, 121, 122, 129, 131, 133, 134, 141, 142, 144, 146, 153, 166, 169, 179, 181, 183, 189, 190, 191, 193, 197, 198, 200, 201, 213, 218, 220, 227, 230, 231, 232, 237, 238, 242, 244, 245, 246, 247, 248, 254, 255, 257, 258, 267, 271, 273, 276, 278, 279, 280, 281, 282, 283, 285, 286, 288, 303, 319, 323, 342, 350, 353, 354, 357, 359, 360, 361, 362, 364, 366, 367, 372, 378, 379, 382, 385, 391, 392, 393, 394, 398, 402, 406, 411, 412, 416, 418, 430, 431, 438, 441, 451, 453, 455, 456, 457, 463, 476, 481, 482, 484, 511, 512, 516, 520, 527, 532, 533, 536, 546, 548, 553, 555, 556, 557, 562, 566, 569, 574, 575, 576, 577, 579, 584, 586, 587, 590, 592, 594, 597, 602, 603, 615, 517, 618, 622, 626, 627, 628, 630, 632, 642, 648, 649, 655, 656, 659, 660, 661, 662, 663, 664, 665, 667, 669, 670, 678, 679, 680, 684, 685, 694, 698, 701, 708, 710, 714, 717, 722, 725, 729, 730, 732, 733, 734, 735, 737, 738, 741, 750, 751, 756, 764, 772, 775, 781, 782, 783, 785, 786, 789, 798, 799, 802, 803, 804, 808, 809, 812, 813, 820, 825, 831, 836, 838, 841, 848, 855, 856, 869, 870, 871, 875, 883, 886, 899, 901, 905, 906, 908, 911, 912, 915, 920, 922, 926, 927, 930, 931, 938, 939, 841, 942, 943, 944, 949, 952, 976, 978, 980, 991, 992, 995, 998, 1000, 1001, 1002, 1005, 1011, 1014, 1016, 1023, 1026, 1030, 1031, 1032, 1033, 1034, 1040, 1044, 1047, 1050, 1054, 1055, 1058, 1063, 1073, 1074, 1075, 1076, 1080, 1084, 1093, 1098, 1100, 1101, 1102, 1109, 1127, 1141, 1144, 1147, 1149, 1152, 1153, 1155, 1156, 1257, 1159, 1160, 1162, 1164, 1167, 1175, 1185, 1190, 1191, 1195, 1196, 1199, 1200, 1201, 1205, 1210, 1213, 1217, 1222, 1224, 1225, 1226, 1227, 1231, 1237, 1238, 1239, 1240, 1241, 1255, 2256, 1263, 1266, 1267, 1270, 1273, 1274, 1275, 1276, 1281, 1282, 1283, 1284, 1285, 1286, 1287, 1288, 1290, 1292, 1294, 1303, 1307, 1308, 1309, 1311, 1312, 1313, 1314, 1315, 1317, 1318, 1319, 1320, 1321, 1322, 1325, 1327, 1333, 1339, 1340, 1342, 1343, 1344, 1345, 1346, 1348, 1349, 1350, 1351, 1352, 1353, 1354, 1355, 1358, 1359, 1360, 1363, 1364, 1365, 1366, 1371, 1372, 1375, 1376, 1383, 1385, 1387, 1389, 1390, 1391, 1393, 1394, 1402, 1403, 1404, 1405, 1406, 1407, 1410, 1412, 1415, 1417, 1418, 1419, 1421, 1425, 1426, 1427, 1428, 1430, 1431, 1432, 1433, 1440, 1444, 1448, 1450, 1451, 1453, 1454, 1455, 1456, 1457, 1458, 1459, 1461, 1462, 1464, 1465, 1469, 1470, 1471, 1474, 1475, 1476, 1479, 1481, 1482, 1483, 1484, 1485, 1487, 1488, 1490, 1497, 1498, 1503, 1505, 1506, 1507, 1508, 1511, 1513, 1514, 1522, 1524, 1531, 1537, 1539, 1542, 1543, 1546, 1554, 1558, 1559, 1562, 1563, 1564, 1566, 1569, 1572, 1576, 1579, 1582, 1586, 1593, 1594, 1610, 1611, 1612, 1615, 1616, 1623, 1625, 1626, 1629, 1630, 1631, 1632, 1633, 1634, 1644, 1646, 1648, 1649, 1651, 1652, 1656, 1658, 1660, 1661, 1662, 1663, 1665, 1666, 1673, 1676, 1681, 1682, 1684, 1687, 1688, 1697, 1700, 1701, 1702, 1704, 1707, 1709, 1711, 1713, 1714, 1715, 1716, 1719, 1720, 1721, 1723, 1724, 1728, 1730, 1731, 1733, 1737, 1738, 1745, 1746, 2747, 1760, 1763, 1773, 1775, 1781, 1785, 1786, 1791, 1802, 1803, 1805, 1806, 1811, 1812, 1814, 1817, 1818, 1820, 1821, 1825, 1828, 1829, 1837, 1838, 1839, 1840, 1841, 1843, 1844, 1845, 1847, 1852, 1857, 1858, 1859, 1863, 1864, 1867, 1868, 1872, 1874, 1876, 1877, 1879, 1880, 1882, 1883, 1888, 1889, 1900, 1901, 1903, 1907, 1911, 1912, 1913, 1914, 1915, 1917, 1918, 1931, 1938, 1939, 1941, 1942, 1943, 1944, 1951, 1953, 1954, 1958, 1959, 1962, 1963, 1964, 1965, 1966, 1970, 1972, 1973, 1974, 1975, 1976, 1985, 1986, 1988, 1989, 1991, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2004, 2006, 2007, 2008, 2009, 2010, 2012, 2013, 2017, 2022, 2023, 2024, 2030, 2033, 2039, 2040, 2041, 2042, 2045, 2048, 2050, 2051, 2052, 2053, 2054, 2056, 2057, 2058, 2059, 2060, 2061, 2068, 2072, 2074, 2075, 2077, 2078, 2079, 2081, 2082, 2084, 2085, 2087, 2088, 2089, 2090, 2091, 2092.

ASSESSMENTS NOS. 44, 45 AND 46.

84, 171, 206, 252, 261, 273, 294, 316, 347, 447, 712, 732, 766, 790, 801, 851, 904, 1057, 1105, 1106, 1107, 1102, 1109, 1110, 1112, 1113, 1115, 1117, 1119, 1120, 1121, 1122, 1123, 1125, 1127, 1130, 1131, 1134, 1135, 1136, 1388, 1432, 1528, 1529, 1530, 1597, 1620, 1622, 1718, 1722, 1750, 1751, 1752, 1753, 1754, 1755, 1756, 1757, 1758, 1759, 1760, 1761, 1768, 1769, 1771, 1772, 1778, 1779, 1780, 1784, 1825, 1895, 1896, 1897, 1917, 1930, 1973, 2025, 2039, 2063, 2064, 2066.

NOS. 44 AND 45.—1770, 1968.

No. 44.—1069, 1187.

The following statement shows the return to the triple assessment of July 15th:

No. 44, for benefit of heirs of Thos. Wilcox, of Chicago, $1,238.
No. 45, " " Edwd. Wade, of Nashville, 1,226.
No. 46, " " R. S. Fowler, of Dubuque, 1,240.

For the first time in our history we will be compelled to issue a quadruple assessment. Four old members have paid their last dollar, and passed away. As they were faithful to their obligations to others, through the four years of their membership, let us, likewise, be true to their memory, and bear, with willing hearts, the burden the death of so many at once entails upon us.

John A. Conley, holder of certificate No. 562, died at Little Rock, Ark., on Sept. 20, of congestion.

M. H. Bacon, certificate No. 459, died Sept. 30th, at Painesville, Ohio, of consumption.

Edwin S. Keep, certificate No. 359, died Oct. 1st, at Albany, N. Y., of consumption.

Alfred Saville, certificate No. 354, died Oct. 7th, of yellow fever, at Shreveport, Miss. The death of the latter was attended with peculiar circumstances, the particulars of which appear in another part of this paper.

Members are again reminded of the seventh annual meeting of our association, which will be held at 145 Broadway, N Y., on Wednesday, Nov. 5th. New officers will be elected for the ensuing year, and other business of importance, reference to which was made in Journal of Sept. 15, will be brought before the meeting.

It is hoped that a large attendance will be secured at this meeting. Many things require thoughtful investigation, especially at this juncture. It seems a crisis in the history of the Association, and it can be met only by mutual counsels and an intelligent deliberation as to the course to be pursued. Let all come.

Alexander E. Hoyt has been appointed agent for the Association at Halifax, N. S. Members in that section will please remit through him as far as may be convenient.

THE Evangelical Alliance has been the cause of considerable care and anxiety in some of our telegraph offices. Owing to the peculiar and technical language in which the speakers occasionally indulged, and the fact that the reporters' copy was often badly written, the operators frequently hesitated and stumbled in transmitting the usual press report of the proceedings. Such words as Œcumenical, Nicene, Ultramontane, Trinitarian, though familiar to polemical ears, were so much Greek to the barbaric knights of the telegraph and the difficulty of reading the copy was greatly increased thereby.

But the difficulties resulting from this great gathering were not alone confined to the trouble of deciphering the reporters' hieroglyphics or professional technicalities. A gentleman out west sent a dispatch to a delegate addressed as follows: John Doe, Evangelical Alliance, N. Y. The message was duly transmitted and delivered, but in checking up the business at the station whence the message originated, the entry clerk searched in vain among tariff books for such an office as Evangelical Alliance, N. Y., and finally gave up in despair and sent a message of inquiry to the Manager of the New York office to ascertain who he should check on message to Evangelical Alliance, N. Y., there being no such office in his tariff-book, either on this or other lines.

CHICAGO MANUFACTURES.

We cannot, in the present number, give an extended account of the Electrical Department in the Chicago Inter-State Industrial Exposition, which opened September 25th. The formal opening was somewhat in advance of the full preparation of the articles for exhibition, but the arrangements are going rapidly forward.

Before the Exposition closes, which will be early in November, we expect to give a detailed account of the electrical apparatus on exhibition from the establishments of *Geo. H. Bliss & Co.* and the *Western Electric Manufacturing Company.*

The articles on exhibition will represent the progress and improvements that are taking place in electric and telegraph instruments.

We may add, in this connection, that the Western Electric Manufacturing Company has grown in its manufacturing department until it is now the largest telegraph instrument manufactory in the country, and is still growing.

The high quality of their workmanship has always made their instruments great favorites with their customers.

The inventive genius of their Mr. Gray has enabled them to place their various specialties in the front rank. But notwithstanding the success of their annunciators, printers, fire alarms, &c., the company finds its principal business in furnishing the standard Morse Telegraph Instruments for commercial and railroad lines.

AWARD OF PREMIUMS AT THE CINCINNATI EXPOSITION.

The following are the award of premiums to the electric and telegraph apparatus on exhibition at the Cincinnati Exposition:

Best system of fire alarm telegraph (in operation); gold medal. J. N. Gamewell & Co.

Fire alarm signal box; silver medal. J. N. Gamewell & Co.

Adaptation of the telegraph to domestic use; silver medal. American District Telegraph Company.

Burglar alarm; bronze medal. American District Telegraph Company.

Best system of telegraphic railway signals; silver medal. Electric Railroad Signal Company.

Best telegraphic instrument for stock quotations; silver medal. Gold and Stock Telegraph Company.

Set of instruments for electrical measurements; silver medal. L. Bradley.

Telegraphic battery, for force, durability and economy; silver medal. Lockwood Battery Company.

Combination of Morse telegraphic instruments; bronze medal. L. G. Tillotson and Company.

Pocket relay magnet; bronze medal. L. G. Tillotson and Company.

Morse register; bronze medal. L. G. Tillotson and Company.

Telegrahic sounder; bronze medal. L. G. Tillotson and Company.

Hotel annunciator, operated by electricity; bronze medal. E. T. Gilliland.

Magnetic watchman's clock; bronze medal. E. T. Gilliland.

Box relay with key attached; bronze medal. Telegraph Supply and Mfg. Company.

Dial telegraphic instrument; bronze medal. Cleveland Mfg. and Supply Company.

Lightning rod; bronze medal. T. F. Randolph.

Electric gas-lighting apparatus; bronze medal. Bachelder Torch Company.

It will be seen that New York carried off twelve of the premiums awarded. The Exposition, which was the greatest and most successful ever held in America, was brought to a close on Saturday, October 4th.

PRESENTATION.

On the 12th of September a number of the shipowners of Yarmouth, N. S., presented Miss Fanny A. Weddleton, W. U. Tel. operator, on her retirement from office, with the following brief address:

"FRIDAY MORNING, Sept. 12th, 1873.

"Please accept the accompanying package from a few shipowners of Yarmouth, as a token of their esteem and their gratitude for the excellent manner in which you so long performed the business of the telegraph office here.

"They wish you much happiness.

"To Miss FANNY A. WEDDLETON."

The address was accompanied by a package, containing a complete set of jewelry and $50 gold—the whole valued at about $200.

The following is Miss W.'s reply:

"YARMOUTH, N. S., Sept. 23d, 1873.

"Mrs. J. Murray Lawson begs to express her heartfelt thanks and gratitude to the shipowners of Yarmouth, who made her so handsome a present on the day of her marriage. But, far above its intrinsic value—great as it is—does she estimate the favorable opinion and expression of esteem by which it was accompanied, and of which it was so substantial and generous a token."

BORN.

WASHBURN.—At Hansells, Ind., Sept. 25th, 1873, to M. E. Washburn, operator J. C. & H. R. R., a son.

MARRIED.

BONNELL—TROW.—At the residence of the bride's father, in Ft. Madison, Iowa, Sept. 18th, 1873, by the Rev. E. . Cady, Geo. W. Bonnell, manager W. U. Telegraph office Ft Madson, Iowa, and Miss Libbie W. Trow, both of Madison.

HARKINS—TUFTS.—In Biddeford, Me., Oct. 6, by Rev. Mr. Rogers, Mr. V. P. Harkins chief telegraph operator of the Eastern Railroad in Boston, and Miss Rose E. Tufts daughter of the late John R. Tufts of Biddeford. Their large circle of friends wish them a pleasant journey and a long and happy life.

LAWSON—WEDDLETON.—At Trinity Church, Yarmouth, Nova Scotia, on the 12th September, by the Rev. J. T. T. Moody, assisted by the Rev. J. R. Campbell, Mr. J. Murray Lawson and Miss Fanny A. Weddleton, of the W. U. Telegraph office, Yarmouth.

SPAFARD—AUSTIN.—At Warren, Ill., Oct. 4th, by Rev. Geo. H. Coit, F. S. Spafard, manager W. U Telegraph office, Warren, Ill., to Miss Hattie Austin, manager P. & A. Telegraph office, Warren, Ill.

WITHINGTON—BRIGGS.—At Springwater, N. Y., Oct. 4th, 1873, by Rev. W. J. Hobbs, Geo. E. Withington, manager W. U. Telegraph office, Springwater, to Laura M. Briggs, of Richmond, Ont. Co., N. Y.

DIED.

SAVILLE.—At Shreveport, La., Oct. 7, 1873, of yellow fever, Alfred Saville, Manager W. U. Telegraph office.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is over 8,000. It goes to every State, Territory and Province on the Continent. It has become a necessity, and is always welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, OCTOBER 15, 1873.

At a meeting of the Directors of the Western Union Telegraph Company, held at the Executive Office, October 9th, the following officers were elected.

WILLIAM ORTON, *President.*

ALONZO B. CORNELL,
AUGUSTUS SCHELL,
NORVIN GREEN,
GEO. H. MUMFORD,
HARRISON DURKEE,
} *Vice Presidents.*

Executive Committee.

WILLIAM ORTON.	JOSEPH HARKER.
JAMES H. BANKER.	EDWIN D. MORGAN.
ALONZO B. CORNELL.	AUGUSTUS SCHELL.
HARRISON DURKEE.	W. K. THORNE.
NORVIN GREEN.	C. VANDERBILT.

FRANK WORK.

To KEEP the service thoroughly informed, it is, of course, essential that the JOURNAL reach every office. This is especially true of new offices, who naturally look to the information provided by the JOURNAL with more than ordinary anxiety and interest. The illness of the Editor, and a sad accident which has recently overtaken him, and which compels him to be, for a time, separated from his duties, may have led to some omissions in the mail entries of the paper. These, it is desired at once to supply. The superintendents are, therefore, requested to mail, at as early a date as possible, *complete lists* of the offices under their charge to which the JOURNAL should be sent. It is also desired that in opening a new office to which the JOURNAL is wanted to be mailed direct, notice be at once given direct to the Editor. These orders will be promptly and carefully attended to, and complaints, now so frequent, may thus be reduced or prevented.

THE attention of Managers is called to the fact, that a special frank is issued to the Directors of the Company, authorizing the free transmission of messages both to and from them. Complaints have been made that, in some instances, such messages have been refused, or charged for. As a list of the Directors is published in the present number of the JOURNAL, there can be no excuse for its recurrence.

A JUST TRIBUTE TO THE INVENTOR OF THE DUPLEX TELEGRAPH.

W. H. Preece, Esq., Divisional Engineer of the English Post-office Telegraphs, and a prominent member of the Institute of Civil Engineers, and also of the newer, but already quite distinguished, Society of Telegraph Engineers, has been publishing, in the *Telegraphic Journal*, a series of highly interesting articles on Duplex Telegraphy, beginning at the very inception of the idea, and coming down through all the various attempts by Gintl, Siemens, Frischen and others, to the successful solution of the problem by Stearns, to whom, in the last number of the *Journal*, he incidentally pays the following tribute. "Duplex telegraphy was thoroughly exhausted in 1856, and with our then means it proved a failure. It has now, thanks to Mr. Stearns, and to our improved means, proved a success; not, however, so much by the reproduction of exploded plans, as by the introduction of methods which are as novel as they are ingenious, and which I shall shortly explain." Words of appreciation like these, coming from so distinguished a source, are very gratifying to us as fellow-countrymen of Mr. Stearns, and must be doubly so to the distinguished inventor himself, to whom they prove that the scientific men of England, who have done so much to advance the science of telegraphy, are not unwilling to accord full credit to their American cousins for what they have accomplished in the same field.

Executive Order No. 150, published in the JOURNAL of August 18th, directed all words following the signature, such as "executor," "manager," "cashier" and the word "answer" or "answer immediately," to be charged for as if forming a part of the body of the message. This simple order seems already to have led to complications in checking, a special check in many cases being given for these added words. There is no necessity for this. The order being understood, the simple statement of the number of words forming the message is all that is necessary. In all such matters brevity and simplicity should be studied, and all methods of work be uniform. Managers will please call the special attention of the operators to this order, so that it may be fully understood by all.

The Telegraphers' Mutual Insurance Association has now been in existence six years. It has done a noble work. Fifty of its members have fallen, four of these within the last few days. Until now there has been no arrest of the prompt payment of assessments. The heirs have been given, without delay, the important aid thus provided and much suffering prevented. Yet, the assessments of the current year have come rapidly. Death has been very busy. We trust the worst is over. Let all take courage. Let the memory of 50 families provided for, and the fact that nearly $40,000 has been freely given by about one-tenth of the W. Union force to the families of their dead comrades, nerve all to bear the burden patiently and nobly. This is a time when those not members might do a generous thing. There are 5,000 men and women who are not members who would do a good thing by sending one dollar each, to strengthen the association, and relieve the pressure upon it. Why not do so?

THE HEROISM OF LABOR.

We have the sad and painful duty of announcing the death of another of the braye band of operators who have fallen victims to the pestilential fever now raging at Shreveport while nobly performing their duty. Alfred Saville, manager at Shreveport, died at twelve o'clock Tuesday night, October 7th, making the fourth death in that office within a month. On the receipt of the intelligence of this death, President Orton sent the following message, whose words of sympathy will be shared by all in the service:

EXECUTIVE OFFICE
WESTERN UNION TELEGRAPH CO.,
October 8, 1873.

JOHN VAN HORNE, *Gen'l Supt.*,
Louisville, Ky.

I can not express my admiration of, and respect for, the men who have sealed their devotion to duty at Shreveport with their lives. The courage which battles with pestilence, to save life and comfort the distressed, is higher and nobler than that which goes to war to destroy it. Please take pains to convey to the family and friends of Mr. Saville, and of the other brave and faithful men who have died there, assurance of my earnest sympathy, which is shared by all the officers of the Company. I desire, also, to be informed as to their family relations, and the circumstances of those who were dependent upon them, to the end that some practical testimony may be given by the Company, of appreciation for the services which these brave and true men have rendered, by an appropriation to meet the necessities of those who have been deprived of the means of support.

It is of no pecuniary interest to the Company to keep the Shreveport office open, as most of the business with that place is done free. But, if others are still willing to face the danger, let neither pains nor expense be spared to keep the lines working.

In view of the fact that our men who go to Shreveport do so in the face of almost certain death, it occurs to me to suggest the propriety of opening an office outside the town, where its benefits will be enjoyed by the people with less risk to our men.

WILLIAM ORTON,
President.

Immediately upon the receipt of the sad intelligence of Mr. Saville's death, the following circular was transmitted by telegraph to all superintendents in the Southern Division:

"LOUISVILLE, KY., Oct. 8, 1873.

It is with the most painful emotions that I announce the decease of Alfred Saville, Manager at Shreveport, La. He died at 12 o'clock last night.

When Rae, and Jackson, and Renicke, our entire force, were stricken down, Mr. Saville, animated, as I believe, by the loftiest motives, tendered his services and proceeded at once to that dangerous post. It was a noble act and has been crowned by a heroic sacrifice.

May he rest in peace and may he receive the reward of the faithful servant.

JNO. VAN HORNE,
Gen'l Supt."

There are still three operators at Shreveport, all of whom have voluntarily tendered their services, viz: Mr. Bernard of Cincinnati, Mr. Davis of New Orleans, and Mr. Smith of Pensacola.

All honor to these noble-hearted men, who, entering upon this unequal contest, tread in the footsteps of the Great Teacher of Galilee and obey at least one of the two commands upon which hang all the law and the Prophets.

E. S. KEEP.

On the face of a tasteful monument erected in the great cemetery of Pere la Chaise, Paris, is an inscription the translation of which is, "The record of his life is his true monument and glory." Thus all men erect their own statues. A life of honor, fidelity, kindness, will be remembered long after the marble fades, and will often live, it may be unconsciously, in the lives of generations yet to come. We know of no subject more fitting for editorial use, and none which we would more willingly impress on the great body of the brotherhood of the telegraph than the following record of a faithful man now gone to his rest :

OBITUARY.

In the death of Edwin S. Keep the telegraphic fraternity has sustained an irreparable loss. Although a man young in years, his experience in the profession extended over a period embracing well nigh the entire history of this distinctively American enterprise—an enterprise whose magnitude no man comprehended at its birth, and whose infancy is scarcely yet at its full. Twenty-two years back, when, as a lad of fourteen, Mr. Keep attached himself to the Troy, N. Y., office, in the capacity of messenger, the Telegraph was little more than an experiment, as to the ultimate success of which serious doubts were entertained, even by liberal and progressive minds. For Mr. Keep the calling had that peculiar and indefinable fascination which many another has felt ; yielding to the charm, he dedicated to its arduous duties the richest days of his life.

With Mr. Keep the ambition to rise in his profession was strong, and in order to achieve this laudable end he was not loth to fulfil its inevitable requirements. Entering the service, at the age of fourteen, as a messenger in the Troy, N. Y., office, at sixteen he was promoted to the duties of an operator in the same office, under the management of Mr. —— Covill ; shortly afterwards he was transferred to Montreal ; close upon the heels of this (those being the days of frequent changes), returning to establish the offices at Millerton and Brewsters, in this State. Subsequently, during his engagement at Philadelphia, Pa., under Manager Bullock, he doubtless laid he foundation of the dread disease which culminated in his premature death : working the almost unprecedented time per diem of from 8 A. M. until 4 A. M. (twenty consecutive hours), for over a year. At this date operators were scarce and companies poor; therefore, in an office having night duties to perform, such additional labor was required of the regular force. The immediate sequence of this exhaustive service was a prostrating illness of nearly a year's duration; after recovering from which, Mr. Keep was, for a brief period, assigned duty at Pittsfield, Mass. At the expiration of this engagement he was transferred to Troy, there to assume the managership of the American Telegraph Company's interests. With the exception of a few months' sojourn in New York, as manager of the Gold Room office of the American Company, Mr. Keep spent the residue of his life in the cities of Albany and Troy, having been, at the time of his death, for seven years manager of the Western Union Telegraph Company's office at Albany, where, by his concise business habits and dignified gentlemanly demeanor, he had gained the confidence of the business public in a singularly marked degree. We cannot, perhaps, eulogize him as a manager, more than to add, that while giving entire satisfaction to the executive officers of the Company, he uniformly retained the esteem and respect of those under his supervision. There is one test which never fails to fathom the sweetest, purest depths of a man's character, and that is his fireside life. Few could stand this test so grandly as could Edwin S. Keep. Those who knew him in his sacred family relations saw the brightest side of his character ; his nature craved affection of wife, children and dear ones, as plant life the electric sunshine. In the last of his hours on earth was the distinguishing trait most apparent. Firmly grounded in that faith which is an anchor to the soul, sure and steadfast, of his own future there was no disturbing doubt; all thought, all concern was for those most dear to him. The hope of heaven was only the more precious to him, from the glimpses of it he had caught on earth. Mr. Keep's conjugal relations were most felicitous. Wedded, at the early age of nineteen, to Miss Eliza Van Schaick, of Troy, N. Y.—she being then eighteen—this twain bravely faced the stern realities of a practical, unromantic life ; to them the task had in it nothing of heaviness ; theirs were light hearts and willing hands, and, too, they had learned early the golden value of "faith," that the darkest clouds have the fleeciest silvery linings. The husband had no secrets from the wife. They met the sunshine and shadows together ; with his family his best and truest life found frank, full expression. None could witness his affectionate and considerate kindness, as a husband and father, without a sensation of the keenest pleasure. Sad as it may seem for one, still so young, to fall as a victim of the remorseless scythebearer, we yet realize that "God's ways are not our ways, nor His thoughts our thoughts." And we sincerely believe that the bereaved family of the deceased will have the deep and heartfelt sympathy of the telegraphic fraternity, and that his memory will be universally revered among us.

At a meeting of the employés of the Western Union Telegraph Company's Albany, N. Y., office, held on Wednesday, October 1st, 1873, the following resolutions were unanimously adopted :

Whereas, It has seemed good to the Disposer of all things to call to his everlasting rest our esteemed manager, Edwin S. Keep, we feel called upon, both by the solemnity of the event and the deep loss we have sustained in the decease of one so beloved and useful, to record our feelings respecting this common affliction, by the passage of the following resolutions :

Resolved, That in the death of Edwin S. Keep the Company has been deprived of a faithful and efficient servant ; that the employés of this office lose a true and faithful friend, and that the city of Albany is bereft of an upright and honorable citizen.

Resolved, That although we shall never more see his commanding form in our midst, his many admirable traits of character have so endeared him to us that his memory will ever be cherished.

Resolved, That while deeply feeling and mourning our loss, we know that language would be inadequate to convey to his saddened and afflicted family the consolation which might soothe them in this their bereavement. We commend them to the care of Him who has said, "Leave thy fatherless children, I will preserve them alive, and let thy widow trust in me."

May the Divine Providence, in its infinite mercy, soften to the sufferers the shock of this sad event, and lift the cloud that has darkened their pathway.

S. C. RICE,
S. C. SHELDON,
J. R. VAN WORMER,

ANTHONY HEDLEY,
} *Committee.*

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York.
October 15, 1873.

To all Offices on W. U. Lines :

On and after November 1st, 1873, unless otherwise directed by special notice before that date, the Local, Square and State Rates (with the exception of the rates named below) will be used on all business between Western Union offices of the Eastern, Central and Southern Divisions west of New Brunswick.

NOTE.—The following list gives the present rates to the points named. It is intended that these rates shall not be changed by the above order:

Exceptions.

Navy Yard, Washington, D. C., 10 cents more than rate to Washington.

Houlton, Me., 25 cents more than rate to Woodstock, N. B.

Astoria, Brooklyn, Flatbush, Fort Hamilton, Hunter's Point, Greenpoint, South Brooklyn and Williamsburg, L. I., 15 cents more than rate to New York City. Offices on Long Island will charge the local or square rates to the above-named Long Island offices.

Birmingham, Alleghany Co., Pa., 15 cents more than rate to Pittsburgh.

Manchester, Pa., 10 cents more than rate to Pittsburgh.

Paxton House, Pa., 45 cents more than rate to Oil City.

Germantown Junc., Pa., 10 cents more than rate to Philadelphia.

The following changes and additions have been made since the date of the last circular :

GENERAL INFORMATION.

Milner, Ala., closed.

Argenta, Ark., closed.

Hereafter the "tariff for other lines" from Little Rock, Ark., to Arkadelphia will be 75 and 5.

Auburn, Ala., closed.

Macon Station, Ala., re-opened ; square 304.

Yosemite Valley, Cal., re-opened ; "tariff for other lines" 60 and 30 from Sonora, Cal. ; check San Francisco.

Telegraph communication with Darien, Ga., is interrupted. Business for Darien will therefore be mailed at Brunswick, Ga until further notice.

Messages may be taken for the Insane Asylum near Milledgeville, Ga., and for Midway, Ga., to be delivered from Milledgeville. Charges for delivery 5 cents for either point.

Carr, Ill., closed.

Atkinson, Ind., re-opened.

Corunna and Millersburg, Ind., are at present kept open at night only.

Hereafter the "tariff for other lines" from Chicago, Ill., to Decorah and Ridgeway, Iowa, will be 75 and 5.

Julien, Iowa, closed.

Linkwood, Md., re-opened.

The P. O. address of Cohasset Narrows, Mass., is Monument Mass.

Burr Oak, Mich., office is at present kept open at night only.

Utica, Mich., is now an Other Line office; "tariff for other lines" 30 and 2 from Detroit.

Douglass, Mich., closed.

Osseo, Mich., closed.

Riga, Mich., closed.

Plaistow, N. H., re-opened.

Asbury Park, N. J., closed.

Lebanon, N. J., closed.

Port Oram, N. J., closed.

Business for Deal, Ocean Grove, and Asbury Park, will hereafter be delivered by stage from Long Branch, N. J. Charges for delivery 25 cents. Charges for delivery should be prepaid.

Hereafter the "tariff for other lines" to Mexico., N. Y., will be 15 and 1 from Oswego, N. Y.,

Trenton Falls, N. Y., closed.

Five Mile Point, Otsego Lake, N. Y., closed.

Overlook Mountain House, N. Y., closed.

Amherst, O., office changed to North Amherst, O.

The P. O. A. of Lawrence, O., (given Laurence in Tariff Book) is North Lawrence, Stark Co., O.

Stryker, Ohio., office is at present kept open at night only.

Clifton House, Ont., closed. Business for the Clifton House can be delivered from Niagara Falls, N. Y., at a charge for delivery of thirty-five cents.

Fort Washington, Pa., closed.

New Cumberland, Pa., closed.

Minnequa Springs, Pa., closed.

Calvert, Texas, closed.

Dekalb, Texas, closed.

Digitized by Google

Sulphur, Texas, closed.
Hot Springs, Va., closed.
Montgomery, White Sulphur Springs, Va., closed.
Sweet Chalybeate Springs, Va., closed.
Blue Ridge Springs, Va., closed.
Sweet Springs, W. Va., closed.

Communications relating to checks or the business of the White Mountain "Summer" offices in N. H., *now closed*, should be addressed to Geo. W. Gates, Dist. Supt. White River Junction, Vt.

The route to Australia, *via Falmouth* and *via Teheran*, is again open, the Madras and Penang Cable having been repaired.

The Cable between Singapore and Hong Kong is broken. Messages for China and Japan must be forwarded for the present *via Siberia*, or mailed at Singapore.

WILLIAM ORTON,
President.

The Galvanometer and its Uses; a Manual for Electricians and Students, by C. H. Haskins, with illustrations. D. Van Nostrand, 23 Murray street, N. Y. 18mo., pocket form. Price, $2.

This work, which comes to us just as we go to press, commends itself, both by its subject, design and appearance, to students of electricity. We quote from the preface as follows: "The author has endeavored to present, in a condensed form, a statement of electrical laws and rules for measurement, written in a plain, brief manner, together with such tables and simple formulæ as will enable any student, with a little practice, to make land measurements with despatch and accuracy." Mr. Haskins is well known as a writer of ability and experience, and has supplied a want which will secure him the thanks of all concerned. See advertisement.

The Eastern Extension, Australasia and China Telegraph Company's traffic receipts for the month of July amounted to £18,190.

EFFECTS PRODUCED BY LIGHTNING AT TROYES, ON JULY 26, 1873.—*M. Parent.*—One interesting feature is the appearance of several balls of fire. One falling before a young woman, rolled along the street, then disappeared; while hair pins, and other pieces of metal about her person, were violently torn out. Other incandescent bodies were afterwards found in a cooled state; one was like a piece of calcined stone, but was surprisingly light; some parts of it were dirty grey with black points, others redish with bright reflection. The lightning produced some curious effects on a public building in the place.

LECLANCHÉ BATTERIES.

CAUTION.

All persons are hereby notified that Batteries

INFRINGING UPON OUR PATENT

are in the market (some of them nearly worthless). The Public are warned against using any such infringement, as in every case the guilty parties will be prosecuted to the fullest extent of the law. The GENUINE BATTERIES have the words "PILE LECLANCHÉ" on the Carbons and Glasses. Any information concerning such infringements will be thankfully received by the

LECLANCHÉ BATTERY CO.,

No. 40 West 18th St.

NEW YORK, Oct. 11th, 1873.

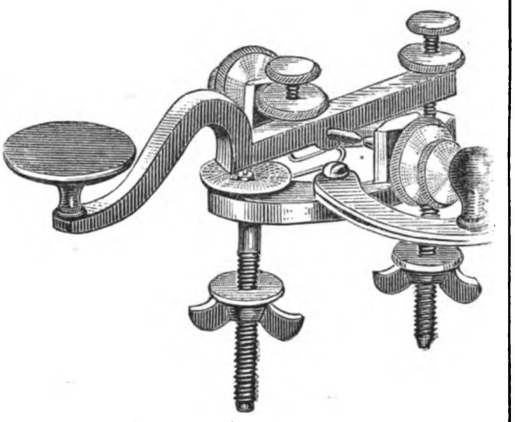
—Recent experiments on the heat of the electric spark indicate that it is between 10,000 and 15,000 degrees Centigrade.

THE FIRST PRINTED BOOK.—The first book ever printed was the Book of Psalms, by Faust & Schaffer, A. D. 1457. It was printed on one side only of the leaves, after which they were, in the binding, pasted back to back.

THE statistical man proves that a person in the United States is six times as likely to kill himself as lightning is to kill him.

The first lightning-rod used in the world for the protection of a building from danger by lightning was set up by Benjamin Franklin, at his dwelling-house, south-east corner of Second and Race Streets, Philadelphia, in September, 1752.

WATTS & COMPANY,



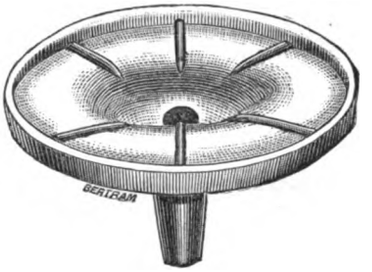
47 Holliday Street,

Baltimore, Md.,

SOLE MANUFACTURERS OF THE

PATENT CIRCUIT-CLOSER KEY,

Which has met with marked success.



Price, $5 50 plain; $7 nickel-plated.

The following is from a competent judge, written after some weeks' trial.

145 BROADWAY, NEW YORK, Sept. 22d, 1873.

DEAR SIR,—Your circuit-closing attachment on the key, left with me for trial, is pronounced by all who have used it a decided and much-needed improvement on the common form.

Respectfully,
A. S. BROWN, *Manager.*

The Best Form of Battery Insulator Offered.

SIMPLE AND PERFECT.

Made of porcelain, handsome in appearance. Occupies little more space than the cell it supports. Each cell of battery completely isolated. Leakage is reduced to the minimum by the use of it.

General Superintendent Van Horn, Southern Division W. U. Tel. Co., writes of it:

"We have now in use a thousand or fifteen hundred of your battery insulators, and expect to order many more before the close of the year.

We have never used any battery insulator that equals it in any respect. In fact, it appears to be as near perfect as we can reasonably expect, in a contrivance for that purpose."

Price 40 cents

We offer a very excellent article of Galvanized Wire, superior to any in the market. The linemen on Baltimore and Ohio R. R. say they have never seen its equal for toughness and flexibility.

Special attention given to building.

Estimates given for any amount of material for telegraph construction or extension.

SWITCHES, GALVANOMETERS, RESISTANCE COILS, &c., to order.

Designs for Switch Boards for special service furnished.

SCOTT'S PATENT ANNUNCIATOR,

for Hotels and Residences.

MANUFACTURE

Telegraph and Electrical Instruments

OF EVERY DESCRIPTION.

Facilities for supplying any description of Machinery or Material equal to any in the United States.

Patented Dec. 31, 1872.

Over SIX THOUSAND cells of the Baltimore Battery in use by the Gold and Stock Telegraph Company of New York in their Private Line Department, is a sufficient acknowledgement of its merit, as a form of the gravity battery, combining the valuable principles of

Economy, Cleanliness and Constancy,

"—in fact a base-burner."

F. L. POPE,
Telegrapher, July 5th, '73.

SELF-FEEDING,

No Sulphate of Copper can reach the Sulphate of Zinc Solution.

The shape of Zinc and Copper, which, with the tube, were patented December 31st, 1872, secures the largest surface with least weight of the metals. Half pound sulphate copper per month, ample supply for No. 2, or 3.

Following is one of the many letters we have from reliable telegraphers:

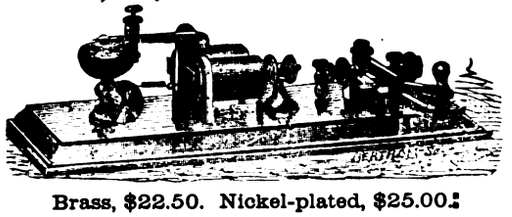
PIEDMONT, W. Va., September 28th, 1873.

Messrs. WATTS & Co.,
Baltimore, Md.

GENTLEMEN:—On January 1st, 1873, I put up 75 cells of your No. 2, Baltimore Battery, in place of 40 cells of carbon, from which two railroad wires of 100 miles each, are supplied. It has not since been taken down or cleaned, and has required no attention, except to fill the tubes with blue stone, once each month, and replenish the fluid once or twice during this period, made necessary by evaporation.

I am fully convinced, from long experience, that this is superior to any other form of the gravity battery.

It has now been in constant use for nine months, and will not need new zinc until after January next.



Respectfully,
J. G. NESBITT, *Manager.*

ORDERS FOR THIS BATTERY PROMPTLY FILLED.

A large stock constantly on hand.

No. 1 for Electro-motors, R. R. signals or similar service,	$2.25
No. 2 ordinary local or Printing Telegraph main	$1.75
No. 3 ordinary main	$1.25

A very Superior Main Line Sounder.

Brass, $22.50. Nickel-plated, $25.00.

For wrecking purposes or temporary offices, this instrument is without a rival.

A perfect combination, handsome, good-sounding instrument.

NO LOCAL REQUIRED.

Well seasoned black walnut box, large enough for pencils, paper, plyers and office wire, in addition to the instrument, $4. Larger size for climbers, vises, &c., $5.50.

RELAYS, SOUNDERS AND KEYS,

always on hand, plain or plated.

Our Challange Sounder is the noisest instrument made.

P. O. Box 6010 *38 Vesey St., N. Y.*

THE LECLANCHE BATTERY CO.

Offer for Sale this celebrated Battery,

(SECURED BY LETTERS PATENT,)

Of which they are the exclusive owners in this country.

Over 300,000 are now in use in Europe,

and have recently been adopted by the French Government in preference to the Calland, which had been used by them for several years.

WE RECOMMEND THEM FOR

Telegraphy (open circuit), Railroad Signals, Hotel Annunciators, Burglar Alarms, Electric Bells, Clocks, &c.

AMONG ITS NUMEROUS ADVANTAGES ARE—

ABSENCE OF ACIDS AND SALTS OF COPPER,

ITS GREAT CLEANLINESS,

WONDERFUL DURABILITY,

ECONOMY IN RUNNING EXPENSES,

ENTIRE ABSENCE OF ODOR.

This Battery will last without any attention from six months to three years.

A large number of Cups are already in use in this country on Burglar Alarms, Electric Bells, &c., and are giving entire satisfaction. The Western Union has a number of Cups put up November 26th, 1872, that are still running.

For further particulars apply to

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 23. NEW YORK, NOVEMBER 1, 1873. WHOLE NO. 144.

ELECTRO-CHEMICAL COPYING TELEGRAPHS.

Copying Telegraphs have never been practically employed, to any considerable extent, in the transmission of messages. The reason of this is partly because they work too slowly to be adopted with profit in the transmission of ordinary messages, and partly because occasions requiring the production of fac-similes present themselves very rarely.

All chemical copying telegraphs are based upon the electro-chemical system of Bain, differing from him, and from each other, only in the mechanical detail of construction.

In 1850, Mr. F. C. Bakewell, of London, brought out his system of copying telegraph, by which dispatches were transmitted in the handwriting of correspondents. In this apparatus (Fig. 1.) a clock-work is supported between the plates, M, M¹, which puts the cylinder, C, in motion simultaneously with the screw, S, of the same length as the cylinder, and carrying a nut, *q*, with style and connection, *r*. When the cylinder is turned by the clock-work, therefore, the style travels up or down the cylinder, according to the direction of rotation of the latter, thereby marking a spiral line whose convolutions are close together.

The dispatch to be transmitted is written on tinfoil, with a pen dipped in varnish. The letters thus written form on the conducting metal surface a number of non-conducting marks, sufficient to interrupt the electric current, though the deposit of resinous matter is so slight as not to be perceptible to the touch.

The message on tinfoil is fixed round the cylinder, C, at the transmitting instrument, which instrument is a counterpart, in its mechanical arrangements, of the receiving one, and either of them may be used to transmit or receive messages. The metal style, *r*, in connection with the battery, presses on the tinfoil, and is carried along by an endless screw as the cylinder revolves, exactly in the same manner as the steel wire that draws lines on the paper on the receiving instrument. The varnish writing, when it interposes between the style and the tinfoil, stops the electric current; consequently, at every part where the electric current is stopped by the varnish at one instrument, the steel wire ceases to make marks upon the paper at the other station. Both cylinders are so regulated that they rotate exactly together; therefore the successive breaks of the electric current by the varnish letters cause corresponding gaps to be made in the lines on the paper; and the succession of these lines, with their successive gaps where the letters occur, produces on the paper of the receiving instrument the exact forms of the letters. The letters appear of a white or pale color on a ground of blue lines, there being about nine or ten lines drawn by the wire to make one line of writing.

Bakewell used an electro-magnetic governor to attain synchronism in the movements of the two apparatus, without which it would certainly have been impossible to have obtained any dependable results.

M. Charles Cros, of Paris, has invented a chemical copying telegraph, which differs in construction from that of Bakewell in the style traveling round the cylinder, instead of the latter turning underneath the style, and in the adjustment of the synchronism six times during every revolution. The apparatus consists of a clock-work, driven by a heavy weight, and giving a horizontal motion to the cylinder, and a rotary motion to an axis carrying the style. The style is fixed to the end of an elbow-piece, and travels round the cylinder, always in the same plane; but as the cylinder, when the apparatus is in motion, is moved sideways, the style describes upon its surface a long line in the form of a close helix. The styles of the two apparatus do not move regularly, but are arrested and released six times in every revolution, for the purpose of regulating the synchronism.

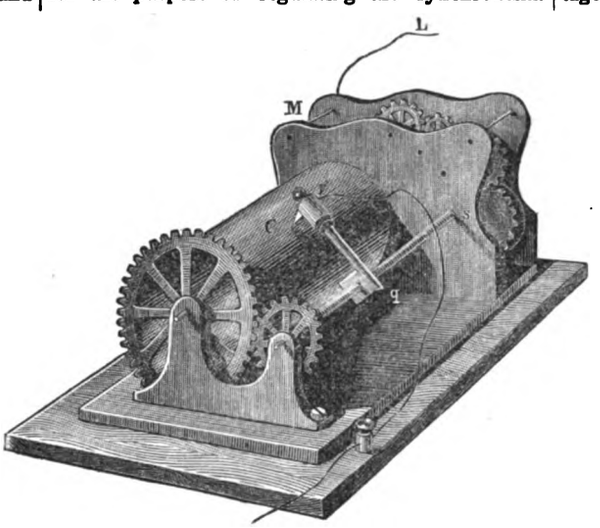

Fig. 1.

When one apparatus goes faster than the other, its style is arrested by the armature of an electro-magnet, until the slower one has come up with it and closed the circuit, which releases them together.

THE CHICAGO EXPOSITION.

During the past three weeks the people of the West and North have had an opportunity of witnessing an exposition far surpassing anything of the kind ever held in this country. One would think that all the inventive genius and mechanical skill of the world had been devoted to the end that Chicago might present to the country an Exhibition, after which Cincinnati, Indianapolis, and other places, which have been entertaining the people with something of the kind, might model with advantage.

Here may be found every kind of labor-saving machinery of which the Patent Office has any knowledge, and every variety of product the soil and climate of America will produce. Here, also, may be seen the wild buffalo just from his native haunts, and the wild duck in his accustomed element.

But your readers will, probably, be more interested in learning what is on exhibition to represent the progress of telegraphy and the novelties of electrical science. This branch of the Exposition is represented by three Companies—the Western Electric Manufacturing Company, Geo. H. Bliss & Co., and the Electric Improvement Company. The Western Electric Company, having much the largest capital and the most extensive shops, of course makes the finest display. This Company was organized but little more than one year ago, yet during that time they have bought the Western Union Telegraph Co.'s shop and machinery at Ottawa, Ill., and added an immense amount of new machinery, much of which was modified and adapted, in its construction, to the manufacture of electrical work exclusively. The advantage of this is seen from the fact, that all telegraph supplies, such as relays, sounders, keys, &c., are turned out almost entirely without manual labor in filing, polishing, boring and screw cutting. In fact, it is like putting the brass and iron into a machine at one end and almost instantaneously taking it out of the other a finished instrument. Under the wise supervision of its President, General Anson Stager, assisted by Mr. E. Gray, superintendent—than whom no better electrician and mechanic can be found—this Company seems to have gained control of the electrical trade of the West.

THE WESTERN ELECTRIC COMPANY.

The space assigned the Western Electric Company at the Exposition Building has been tastefully fitted up, and everything so conveniently arranged that visitors can examine in detail the construction and working capacity of every article. As we approach the stand, an elegant show case first attracts attention. In this may be found Morse telegraph machinery, of every style and finish—brass mounted and nickel plated, rubber-tipped and ivory-pointed; common relays, box relays, local sounders, keys, cut-outs, switches, and everything calculated to invite a current of electricity from the battery to the line.

To the left of this we find Hamblet's Electro-magnetic Watch Clock, adapted to keeping a record of the movements of watchmen around buildings during any number of hours they may be on duty, and at the same time run any number of dials attached thereto.

GRAY'S PATENT PRINTERS.

Leaving this, we are confronted by a set of Gray's Patent Printers, connected into a circuit to better exhibit their merits. This instrument requires no description; its general use on hundreds of private lines in the West has established its superiority over every other printing instrument, and the demand in

Digitized by Google

the East, I understand, is at present greater than the Company can supply. The advent of this printer numbered the days of dial instruments, and laid them up as relics of the past. Two of these instruments on exhibition are elegantly nickel-plated and highly finished, and are perhaps as fine a piece of workmanship as can be found in the building. One fact may be mentioned in regard to these instruments, showing how well they are adapted to the use of private individuals, and that is: since the opening of the exhibition they have been in constant use from morning until night, played upon by boys attracted by curiosity, who never saw anything of the kind before; yet, under all this rough usage, they have not been the least out of repair.

NEEDLE HOTEL ANNUNCIATOR.

The next prominent object is a Needle Hotel Annunciator. The superiority of this pattern consists in its simplicity, having no complicated machinery to get out of order. The numbers are restored by a mechanical motion, the handle for which may be placed at any desirable distance from the Annunciator. In connection with this may be seen a device for detecting a fire at its earliest inception, in hotels or other large buildings, and is called the

MERCURIAL ELECTRIC FIRE ALARM.

It is automatic in its operation, and never fails to give the exact location of the fire. It consists of a small glass bulb, having two upward tubes with a platinum wire in each. The bulb is filled with mercury and one of the wires connects with it. The other wire does not touch the mercury unless the latter is expanded by heat, when an immediate alarm is given.

A pair of Hamblet's Magneto-Electric Dial instruments are also on exhibition, but the success of the Printer detracts somewhat from its merits, and will doubtless preclude its extensive use.

One of the greatest objects of interest to the visitor, and, perhaps, the finest piece of electrical work presented, is

A MAGNIFICENT SWITCH BOARD

and massive frame, constructed for the United States Naval Observatory, at Washington. The board has a capacity for sixty wires, and in style and finish excels anything of the kind ever made in this country. The frame is of black walnut, elegantly carved, six feet wide by ten feet in height, and surmounted with the monogram of the Observatory.

Adjoining this may be seen A LARGE PHONOGRAPH, recently made to order for the Chicago Observatory. The workmanship displayed upon this is in keeping with the reputation of the Western Electric Company for beauty in design and unerring certainty of operation.

I will not trespass further upon your space with a description of articles in this line, although there are numerous other objects claiming the attention of telegraphers. You may see BATTERY MATERIAL of every kind, including Grove, Calland, Bi-chromate, Laclanché, Smee and Maria Davy, the aggregate making a respectable battery of artillery; insulated wire, from No. 10 to No. 50; insulators of every size and pattern, while with climbers, pulleys and eccentrics, one would think the stock complete.

THE TYPE WRITER.

I had almost neglected to mention the Type Writer. This instrument, patented by Sholes & Glidden, of Milwaukee, Wis., really possesses great merit. In size and shape it is similar to a sewing machine, and is manipulated by a key-board, after the style of the piano. Its capacity is from 75 to 100 words per minute, and is invaluable in every counting room or other place where much copying is to be done.

The Exposition will probably not close for two or three weeks, and those of your readers who have time will never regret the visit, should they atten .

FESTUS.

RECORDING MUSIC.

AN ELECTRIC APPARATUS FOR RECORDING MUSIC WHILE BEING PLAYED.

Efforts for the constructiou of a machine by which music played upon the piano or organ could be reproduced upon paper have been frequently made, but thus far without practical success, at least as far as the organ is concerned. So many musicians find that in moments of inspiration they draw from the instrument sweeter strains and more delightful music than they ever could transfer to paper, that the desire for such a contrivance has been long and universally felt. This need seems now about to be met by a contrivance which Mr. Barnes, a machinist of Bridgeport, Conn., aided by Mr. Guernsey, a manufacturer of electrical machines in Jersey City, is now constructing, to be attached to the organ in the hall which C. T. Shelton, of New Haven has built for his son, Willis C. Shelton, the boy organist. The apparatus is nearly completed, and will be tested at no distant day, and no doubt a description of it will be interesting alike to musicians and machinists.

The organ is connected with the recording apparatus by a magnetic telegraph, and its operation is very simple indead. Beneath each note of the three manuals and of the pedals, and connected with each stop of the organ, is a small brass spring, which is pressed down whever the piece to which it is attached is brought into action. From each spring wires run to a galvanic battery of 12 cells, and to the recording apparatus, which may be situated at any convenient distance from the organ. When the spring is pressed down, connection between the battery and the recording apparatus is formed, and the electric current passes through. The recording apparatus is very simple and similar to that used in Morse's telegraph. Attached to clock-work, by which a uniform motion is produced, are two cylinders some 18 inches in length, between which is carried a strip of paper divided into about 250 longitudinal divisions—one for each note and stop in the organ. Corresponding to each of these divisions is a magnet whose armature carries a lever armed with a style, which indents the paper as long as the electric current is passing through. Now when any note or stop is brought into action the spring connected with it is pressed down, the circuit is completed, the corresponding armature is attracted to its magnet, and the division of the paper belonging to the note struck is indented with a line proportionate in length to the time during which the note is held down. A staccato touch will be represented by a simple dot, while a longer tone will be recorded by a more prolonged indentation. The clock-work is so geared that the paper is carried forward on the rollers at the rate of about one-half an inch per second, thus recording each note in the most rapid playing at the rate of about ten notes per second by a line one-twentieth of an inch in length and longer notes by lines proportionally extended.

The apparatus is simply an immense House's telegraph, except that the symbols are distinguished by their position rather than by their form. It is estimated that about 12 miles of insulated wire will be used in the construction of the machine, and the clock-work is set in motion by a weight of about 500 pounds. The difficulties which the inventors encountered in constructing a machine which would successfully record all the movements of a rapid organist were very great, and many other points were tried before the present one was finally hit upon. A number of experiments were made with a machine operating on the principle of the Bain telegraph, in which the electric current discolors a chemically prepared paper; but it was finally abandoned as inexpedient.—*N. Y. Tribune.*

CURIOUS ELECTRICAL PHENOMENON.

A party of surveyors belonging to the United States geological survey expedition of 1872, had a novel experience on the summit of a peak near Cinnabar mountain. When they were within five hundred feet of the top, a storm came up and they were enveloped in clouds. The ascent was very difficult, as the fragments of rock were sharp, and most of them loose, sliding from beneath the feet of the party as they clambered upward. One of the company, however, succeeded in reaching the highest point and depositing his instruments, when he discovered that he was in the midst of an electrical cloud, and his feelings not being of the most agreeable sort, he retreated. As he neared the remainder of the party, they observed that his hair was standing on end, as though he were on an electrical stool, and they could hear a series of snapping sounds, as if he were receiving the charges of a number of frictional electrical machines. Another member who attempted the ascent soon received a shock which deterred him. The peak was appropriately called Electric Peak. Its altitude, as measured the following day, is 10,992 feet above the sea.

THE INFLUENCE OF CLIMATE UPON LIFE.

An interesting article appears in the *Gazette Medical de L' Algerie* on the influence exerted by climates in regard to health and life of foreigners. In that article we are reminded that the negroes of Senaar recruited by Mehemet Ali for his army, speedily succumbed after arriving in Egypt; that negroes of Central Africa rapidly die if transported to Arabia, and that if sent to Europe they perish by phthisis. Of 1,800 negroes sent to garrison Gibraltar in 1817, nearly all are said to have been destroyed by pulmonary consumption in fifteen months, and of the negro convicts sent from the French colonies to the hulks at Brest, one-fifth die each year. In Mexico, the Egyptian contingent suffered by disease and death in larger proportion than did the regular troops from France; whereas Algerians and Arabs in France enjoy relatively better health than in their native countries. During the Russian war the Zouaves and Turcos resisted the climate of the Crimea better than the men of the French heavy cavalry, and, it is said, that on the same occasion the Algerian horses withstood the severe Winter even better than those of the English cavalry. With regard to the power of resistance of Arabs, as illustrated in the war of 1870–71, it is observed, that if in battle they become excited to paroxysms of fury, once wounded, or taken prisoners, they find in their complete belief in fatalism a source of moral calm and resignation. The Arab, moreover, is less sensitive to pain than the European; hence, in a great measure, the principal cause of the faculty with which wounds received by the former heal.—*The Doctor.*

THE cable of the Western and Brazilian Telegraph Co. from Perambuco to Para has been successfully laid, and the cable steamer Hooper will leave about Nov. 1 to submerge the sections of cable from Pernambuco to Bahia, and from Bahia to Rio Janiero.

GREENWICH TIME.

Never had science a more pleasant retreat than Greenwich Observatory appears to be this bright summer morning.

For all its pleasant aspect, however, the idea of exploring it is decidedly a formidable one. At the very entrance gates one feels suddenly convicted of the most abject ignorance. Here are mysterious metal pins fixed on the wall for the determination of British measurements, and the question at once arises, What have these to do with astronomy? Then there is a great clock-dial on which the hours are reckoned from one to twenty-four, and which is popularly believed to be kept going by the sun.

Determined to clear the way as he goes on, the visitor makes these outer difficulties the subjects of his first inquiries on gaining admittance, and he discovers to his amazement that the very length of his trousers, and the cut of his coat, and the height of his hat have all been determined by measurements based upon the motions of the heavenly bodies.

A tailor's yard measure, it appears, bears a certain proportion to the length of a pendulum which, under specified conditions, beats accurate seconds of time, and seconds of time are determined by astronomical observation. If the tailor wishes to verify his measure he has only to bring it to the Observatory gate, where he will find a standard absolutely accurate.

As to the clock, it is an astronomer's clock, and astronomers know nothing of A. M.'s and P. M.'s; their calculations are sufficiently complicated without them. The notion that it is kept going by the sun is, it need hardly be said, a mere delusion.

On passing the outer portal of the Observatory, the visitor finds himself in an open courtyard, with an irregular pile of buildings on his left hand. Entering a low doorway in one of these, he is at once interested to discover that he is really at what may be considered the fountain-head of all our computations of time. The chief business of Greenwich, as all the world knows, is to tell us the time of day, and in this small and somewhat mean-looking apartment is the great telescope by which observations for this purpose are effected.

This instrument—the transit circle, as it is technically called—is twelve feet in length, and its largest glass is eight inches in diameter. It is suspended by the middle between two massive stone buttresses in such a manner as to permit of its sweeping the sky in a straight line overhead, though it cannot be veered round to the right or left.

We have arrived, let us suppose, a little before noon; the sun is about to cross the meridian, and an observation is to be made. Shutters in the roof are thrown open, the great telescope is swung up and fixed in position, and an observer seats himself at the lower end of it. While we are waiting for the great lumiuary, let us take a peep through the instrument. All that can be seen is a number of vertical lines—technically called wires, though they are in reality so many pieces of cobweb—stretched across the field of observation at irregular distances. The centre one is the celebrated meridian of Greenwich, or at all events it represents it, and it is curious to reflect that from this centre line ships of all civilized nations, and in all parts of the known world, are reckoning their distances; that this little piece of cobweb is, practically, all that divides the world into eastern and western hemispheres.

While we are peering along the telescope, the drowsy tinkling of innumerable clocks is heard through the still summer air, and we begin to think that for once at least the sun is behind time. If not, then it seems plain that all the Greenwich clocks are wrong, a supposition which is quite at variance with all our traditional ideas of the place. On inquiry, it is gratifying to find that our faith in Greenwich timepieces is perfectly justified, and that it really is the sun that is behind time. The apparent motion of the sun, as everybody knows, is really the motion of the earth. Now the earth moves round the sun in a kind of oval pathway. When she is on either side of this oval her motions are accelerated, and the sun will cross the meridian before he is due. Just now, however, we are at one end of the oval, and the earth moves slowly, and, as we see, the sun is behind his time. It is clear, therefore, that if the Greenwich clocks were to be regulated according to the time at which the lord of day puts in an appearance at this little cobweb, they would require constant alteration. They are, however, set to record the average time of his transit. This never varies, and twelve o'clock "Greenwich mean time" is simply the mean or average time at which throughout the year the sun crosses the meridian.

Let the observer now resume the watch at the instrument. What he has to do is to record the precise instant at which the sun's edge or "limb," as astronomers express it, passes that central "wire." In any single observation, however, he may be a little at fault, and for the sake of greater accuracy, therefore, he will note the instant at which it passes over all the "wires," and then strike an average between them.

Slowly the sun creeps up to the first line, and the observer lightly taps a little spring attached to the telescope. The second "wire" is reached, and again the spring is tapped, and so on throughout the whole of the seven or nine webs employed in the observation.

This spring is connected with a telegraphic wire extending to a "chronograph" in a distant part of the building; and in order to understand the method of recording the observation, we will now follow the telegraphic signal, or as imagination is even swifter than the telegraph, we will imagine that we have reached the "chronograph" first, and and are there ready to receive the signals.

Accordingly we find ourselves in a queer little chamber, in which the most prominent object is a very beautiful specimen of a clock whose pendulum, instead of oscillating backwards and forwards, swings round in a circle, thus producing a motion perfectly uniform and unbroken. This clock is revolving the "chronograph," which consists of a cylinder around which a sheet of white paper has been strained. While we are watching this revolving barrel, we see the observer's signals come. A little steel point, which is traveling over the surface of the paper, is in electric communication with the spring attached to the great telescope; and every time the observer taps the spring, this little traveling point pricks into the paper, thus recording that the sun has just crossed a "wire." This in itself, however, would not be a record of the time of transit if it were not that another little steel point, which is in connection with a galvanic clock in another part of the building, has previously marked the sheet of paper into spaces representing the precise seconds of time. On the completion of the observation the paper may be reserved from the cylinder and affords a permanent record of it.

Nothing perhaps throughout the Observatory at Greenwich is calculated to strike the visitor with greater astonishment than that galvanic clock to which reference has just been made. There is nothing very remarkable in its appearance, but the work it accomplishes renders it perhaps the most wonderful clock in the world, and certainly the most important one in England.

In the first place, as we have seen, it plays an important part in registering observations. Besides this, it regulates several clocks within the Observatory, as well as the large one already referred to outside the gates; one at Greenwich Hospital Schools, another at the London Bridge Station of the South Eastern Railway, another at the Post-office, St. Martin's-le-Grand, and another in Lombard Street. Once every day it telegraphs correct time to the great clock tower at Westminster; it drops the signal ball over the Observatory, another near Charing Cross and one at Deal; it fires time guns at Shields and Newcastle, and every hour throughout the day it flashes out correct time to each of the railway companies. All this is accomplished as it were by the mere volition of the clock, and without any human interference whatever. Every morning it is corrected by an actual observation of a star; and thus, without being aware of it, we start our trains, and make our appointments, and take our meals by the motions of the heavenly bodies as observed and recorded during the preceding night.

We now proceed to one of those curious little domes surmounting various parts of the Observatory. Here we find an instrument devoted entirely to the study of the moon. Observations of the moon are of immense importance to us as a nation of navigators, inasmuch as she affords the means of determining longtitude at sea. Her motions, however, from various causes, are of an extremely complicated nature, and it is very necessary that she shall be observed at all times, and under all circumstances. But with the transit circle, the instrument first noticed, it is plain that the moon could be observed only when she is crossing the meridian, and not always then. Some five or six-and-twenty years ago, therefore, Sir George Airy, the present Astronomer Royal, designed the "Altazimuth," and since then the importance of Greenwich as a lunar observatory has been just about doubled.

With this instrument and the transit circle the Observatory might do all that, strictly speaking, comes within its province. The whole duty of Greenwich, as defined by Herschel, is "to furnish now, and in all future time, the best and most perfect data by which the laws of the lunar and planetary movements, as developed by theory, can be compared with observation. Mensurative astronomy for practical purposes is the great business of Greenwich.—*Cassell's Magazine.*

WROUGHT IRON TELEGRAPH POSTS.

Telegraph posts and columns manufactured in Manchester are formed of spirals of iron—ribbons, in fact, supported on a cast iron base, and surmounted with a capital of the same material. A slender rod from the axis of the column, or, as it really is, a trellis work tube. Compared with cast iron columns these structures are little more than one-third either in weight or cost, while in appearance the gain is decidedly great. For conservatories or other horticultural purposes the trellis column is very suitable. Such a pillar, eleven feet high and eight inches in diameter, is guaranteed to support a vertical pressure of one ton.

ON September 10, the New Swedish-Danish-English telegraph line was opened to business, by which Sweden has been placed in direct telegraphic communication with Great Britain. At the same time a new line has been opened between Gothenburg and Fredericia, through which Sweden has been placed in direct connection with the Danish-French cable. Gothenburg is the termini of two new lines in Sweden, for which reason the Company have selected it as a cable station.

NON-RESISTANCE OF THE EARTH AS A CONDUCTOR.

Steinheil, in 1837, was the first to employ the earth as a substitute in a telegraphic circuit for the return wire. He buried two copper plates in moist earth, one at each station, and connecting the extremities of his telegraphic lines to these plates, and found that signals could be transmitted with as much facility as when a return wire was used. In fact, as proved by Wheatstone, in 1841, the same battery will work to a far greater distance with a circuit half wire and half earth than when altogether wire. In 1844, Matteucci, by an experiment in which he caused the current from a single Bunsen cell to flow through a copper wire 9,281 feet in length, and through the same length of moist earth, found that the earth conducted so much better than the wire that its resistance must be regarded as nothing. Bréguet also found on the telegraph line between Paris and Rouen, that when the current traversed a circuit half metal and half earth, the intensity was twice as great as when the circuit was metallic throughout.

Two explanations have been given of this non-resistance of the earth: one, that as the conducting power increases in proportion to the area of a section of the conductor, the earth, acting as a conductor of infinite area, offers a smaller amount of resistance than the metallic part of the circuit; the other, that the earth acts as an immence reservoir which absorbs all the electricity poured into it.

THE British Government have purchased the lines of the telegraph companies at a cost of £5,847,347. The additional sum of £586,853 has been paid for the lines of 28 English and Welsh railways, besides contracting to pay various sums annually for rights of way or "way leave." Twelve Scotch companies have been recently contracted with for about £275,000. Forty-four railway companies still remain unsettled with, most of them involving large amounts. Mr. Scudamore's original estimate was £3,000,000. The *Railway News* remarks: "To the sums paid, and to be paid, must be added the cost of alterations and extensions necessary to concentrate the separate systems. When all these matters are settled, we shall not be suprised to find the aggregate cost represented by a capital sum of twelve millions sterling (equal to $65,000,000), or four times the amount of the original estimate."

FOUCAULT has invented an apparatus for measuring the velocity of light, which includes a small wheel that can be run at the rate of 60,000 revolutions a minute. The wheel carries a diminutive mirror, which at first was of the ordinary kind; but the great speed quickly stripped the amalgam from the glass, and a metallic mirror had to be substituted.

THE science of *Electricity* has met with the loss of one of the veterans in that department, Sir Francis Ronalds, whose death, in his eighty-sixth year, was recently announced. A work of great labor, including the history of the development of the science of electricity, is announced as having been completed by him shortly before his death, and will be looked for with great interest. He established, in 1823, a working electric telegraph through eight miles of wire.

THE influence of the electric current on germination and the growth of young plants, has been studied with much care and discrimination by Bridgmann, who finds that positive electricity promotes the upward growth of the roots, and leaves the seeds blackened and dried up, while, on the other hand, negative electricity promotes the downward growth of the roots, and maintains the seeds in a fresh and plump condition. Both positive and negative electricity, however, stimulate the growth of the young plant to a degree far surpassing its natural rate of development.

RELIGIOUS ELECTRICITY.

Recently, in New York City, at the dedication of the new and splendid Jewish synagogue, corner of Lexington avenue and 53d street, a portion of the first chapter of Genesis was sung by the choir; and as the words "Let there be light and there was light," were uttered with a grand burst of melody, the whole church was instantaneously lighted up by electricity. Thus it is that modern science lends her aid to give effect to the solemnities of her servants.

PROTECTION OF SHIPS' COMPASSES.

The possibility of protecting ships' compasses from the disturbing effects of the varying action of the iron on the vessel has led several eminent electricians to devise means to secure this result more or less perfectly, and the latest suggestion is that of Mr. Gloesvenor, member of the Royal Academy of Brussels, who proposes to place the standard compass on a prolongation of the bowsprit of the vessel, in this way securing the advantage of having all the disturbing iron on one side of the needle, and placed symmetrically with reference to it. The necessary length of the prolongation Gloesvenor finds by experiment to be twenty-five or thirty feet. To read the compass conveniently, he puts a mirror above it, in which a person standing on the deck may read the needle or compass card. A small fixed telescope facilitates the accurate observation.

BECQUEREL ON THE NATURE OF ELECTRICITY.

Becquerel, as the conclusion of long research on the electrical forces, says that "in the present state of our knowledge of physics and chemistry, it is scarcely possible to attribute to chemical affinities an electric rather than a calorific origin. What, then, is their origin? Time will answer. They are connected probably with universal ether. Let us study all the causes that exert an influence upon these affinities. This is the only way to effect the removal of the veil that covers this mystery."

THREE Telegraph companies, viz., "The River Platte and Brazil," "The Western and Brazilian," "The Montevedian and Brazilian," have united their interests, and have agreed to lay a cable along the coast of Brazil, touching at the following stations: Santos, Santa Caterina and Rio Grande. The Western and Brazilian Telegraph Co. had agreed to lay its cable from Rio de Janeiro to Bahia and Pernambuco, where it effected a junction with the cable to Europe of the Brazilian Submarine Telegraph Company, and thence proceeded to Para; while the Montevidian and Brazilian Tel. Co. had agreed to lay its cable from the frontier of Brazil to Maldonado, and thence to Montevideo. By this arrangement, these companies become a part of the Great European-Brazilian Telegraph system, with exclusive privileges of a character regarded as highly valuable. It is a union of the South American lines with England.

A DEVICE has been published by Sortais for detecting the occurrence of leakage in ships, an electrical arrangement being used, which is so constructed as to communicate to the captain, on a dial in the cabin, information of the slightest occurrence of anything of the kind, and the extent to which it has proceeded.

THE preliminary arrangements for the Black Sea cable from Odessa to Constantinople are completed.

THE Queensland House of Assembly has determined on the construction of a cable telegraph from New Zealand and New South Wales.

We regret to record the death of the amiable wife of Mr. George C. Wood, Manager W. U. Tel. Co., Fort Plain, N. Y.

A GOOD SUGGESTION.

To the Editor of the Journal of the Telegraph:

DEAR SIR: The piece in JOURNAL of September 15th, by J. H., in regard to advertising, seems to me to be a good idea, and in addition I would suggest a few plain rules for the public in regard to sending a telegram. There is a diffidence among many about using the telegraph on account of not knowing how to get about it, and what it is going to cost. I charged a wealthy farmer twenty-five cents for a message and he asked how that was, as he had received one which was marked "paid 9" and must have cost but 9 cents. I explained that it was probably marked "9, paid," which denoted the number of words and not the price. Let the calendar contain something like the following:

Write messages plainly, spelling words and numbers out in full.

Give full address, as address and signature cost nothing.

Ten words cost no more than a less number.

Be particular to write proper names very clear.

Very respectfully,

J. E. BROWN, *Operator.*

USE OF ARMATURES APPLIED TO MAGNETIC BUNDLES.—*M. Jamin.*—If several magnetized plates are superposed they react on each other, each destroying, in part, the magnetism of its neighbor; so that the portative force of the bundle is less than the sum of the forces of the plates considered separately. M. Jamin has found a means of preventing reaction and weakening for a time. He magnetizes each plate separately; applies to it a well-fitting contact of the same thickness, which neutralizes it; then superposes plates and contacts, fixing with screws the magnets together and the contacts together. This does not destroy the neutrality of the elements, but hinders their reaction. Thus to detach all the contacts a weight of 115 kilogrms. was necessary, or a little above the sum (108) of the individual forces. Immediately the contacts are detached the plates cease to be neutralized; their magnetism reappears; they react on and weaken each other as before. Superposed plates with an armature are less charged (magnetically), and so react less on each other. Armatures weaken the magnetic intensity; their par is to offer a space where magnetism may collect and be preserved, which would otherwise be destroyed in consequence of mutual reaction between the constituents of the bundle.

THE steamship Hibernia, of the British Maintenance and Construction Co., is reported taking in the cable of the Brazilian line from Madeira to St. Vincent. The Kangaroo is also loading the cable, for Jamaica and Colon, for the West India and Panama Co. The Africa sailed two weeks ago to complete the system of cables in the Levant by a line from Alexandria to Candia; from the latter island to Zante, and an additional one between the Greek Archipelago and Italy, thus giving another route to the East from Europe, and uniting Turkey in Asia with the great submarine telegraph system.

ON THE MULTIPLE CAUSES THAT PROVOKE THE DISCHARGE OF LIGHTNING—*By M. W. de Fonvielle.*—Having rapidly enumerated the causes relating to the form, nature, and situation of the objects struck, M. Fonvielle seeks to show that two neighboring conductors react strongly one upon the other when they are under the influence of a storm-cloud. He seeks to establish that this reciprocal influence is not the same in the case where the two conducters are insulated, or when they are placed in connection with the common reservoir, either the one and the other, or the one or the other only. It is known that an electrified cloud acts by induction on all the objects which it covers, but, as M. Fonvielle believes, no one has yet remarked that by the fact of its movement the electrified cloud produces special reactions. According to him, it acts in the same manner as the revolving plate of a Holtz machine, which by its movement at a distance of an induced body, produces, as we know, an energetic disengagement of electricity. M. Fonvielle seeks to draw some practical conclusions from this assimilation, which appears to him to explain how it is that insulated conductors, placed to the south-west or north-east of considerable masses with a common reservoir, are more frequently struck. He hopes to arrive ultimately at experimental proof of all these theoretical deductions, by the aid of a special register for condensing lightning conductors, of which he has already had the honor of laying a notice before the Academy at the commencement of January last. M. Fonvielle enumerates certain phenomena, such as the rise of the sea, which seem to show that the attraction of the clouds is powerful enough to make itself perceived on the surface of the earth. It appears to him necessary to conclude from this, reciprocally, that the influence of the surface is sometimes powerful enough to modify the pace of the clouds, so as to impart to them in certain cases a greater velocity before they reach the zenith of the object influenced. Changing greatly their character, the attractions can, in other circumstances and particularly until there is no electric discharge, diminish the velocity of the clouds after they have passed the zenith of the electrified object. In short, these attractions and repulsions, of which we have too long neglected to take account, place themselves in juxtaposition to the movements produced by the primitive Newtonian attraction and repulsion as the displacement of the clouds are combined with the general action of the wind. M. Fonvielle concludes by remarking that the modifications stated in the value of the terrestrial magnetism, consequent upon the movement of the stars, are analogous to those which the clouds produce on the electrification of points of the earth's surface. In all the cases, the electric forces developed incontestably proceed from the transformation of dynamic efforts, be the motor the wind or any known or unknown cause of movement.

"JOHN" writes from Fort Dodge respecting a plan for separating the metals in the Hill Battery, instead of Mr. Haskins' plan of casting the supporting wire, which "John" says every one can't do. "John" proposes a crib made of small sticks, three being upright the length of the amount of separation needed, the others laid across to keep the uprights in their places. But "John" has no Hill battery, and doesn't know how his plan will work, and so we punish "John" for writing about what he has not proved, by withholding his communication. We have, however, given his plan to whoever may please to try it, but which we don't commend.

SHARES of the Globe Telegraph Co. are now in the lists of the London Stock Exchange.

A FAMOUS TELEGRAPH OPERATOR.

Among the victims of the fever at Shreveport was Alfred Saville, one of the best known and most accomplished telegraph operators in the country, and attached to the command of General John H. Morgan during the late war. Few have forgotton how, early in the game, he took possession of the wires between Nashville and a body of Federals operating in Southern Kentucky, giving peremptory orders not to send any more troops, but plenty of provisions and ammunition, and an old friend, then in charge in Nashville, detecting the peculiar touch or fingering of the bogus operator, flashed back to him this good-humored answer: "Get out, Saville, or I'll send the cavalry after you."

Saville volunteered his services at Shrevesport after every resident operator had been stricken down, and died at his post.

A TELEGRAPHIC SOCIAL UNION.

TRENTON, N. J., Oct. 16, 1873.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—George W. Zeigler, operator on the Belvidere and Delaware Railroad, and son of the proprietor of the Union Hotel, Lambertville, N. J., gave an entertainment on Tuesday evening, October 14, to his associate operators of the Pennsylvania Railroad and to a number of invited guests. At 9.30 P. M. about fifty sat down to a bountiful repast. Mr. J. C. Hankinson, of Trenton, presided. A telegraph instrument stood beside him, from which a wire was connected, running up the Belvidere and Delaware Road, with which Mr. H. kept up commucation with operators on the line, under the eye of our genial superintendent, Robert Stewart. At the conclusion of the repast, speeches were made by A. C. Davis, J. E. Moon, R. B. Reading, J. C. Hankinson, C. P. Curtis, C. W. Wellington, and a host of others, after which a meeting was organized in the reception room, by the appointment of Robert Stewart, chairman, and James E. Moon, secretary. A committee, consisting of Jesse R. Mills, T. F. Skillman and R. R. Reading, reported the following resolutions, which were unanimously adopted:

Resolved, That the thanks of the operators of the Belvidere Division, Pennsylvania Railroad Co., and the invited guests, are due and are hereby tendered to George W. Zeigler for his handsome entertainment of this evening.

Resolved, That the pleasure we have received on this occasion is largely due to the ladies, for their kind and unremitting attention and graceful and kindly presence.

An hour or two was then spent in the enjoyment of vocal and instrumental music, contributed by H. Barber, E. Gallagher, W. W. Angel, C. H. Green, R. B. Reading, C. W. Wellington, C. A. Davis, J. M. Lewis, C. P. Curtis and W. W. Currier of Boston, all telegraphers, and in the small hours of the night the guests separated to their homes by special trains to Trenton and up the river. MILLS.

A COMMUNICATION signed "Amicus" desires the talent now employed in discussing changes of Alphabet to be used in advocacy of a new Tariff Book. This is scarcely a topic for discussion in the JOURNAL. The true plan is to communicate with the superintendent, one of whose duties it is to watch the necessities of the service and facilitate office labor. For us to discuss such subjects seems like unnecessary interference with executive duties.

NOTES AND QUERIES.

Suppose we should take in a message of twelve words at 50 and 3; total, 56c. Should we collect 55c. or 60c.?

Answer.—Collect 56c.

How many words in following message: "Shipped goods in car No. one hundred and thirty five (135)? Please answer through the JOURNAL.

Answer.—Fifteen words.

For the instruction of others, please say whether or not to do as follows is correct An office on this road receives a red message some time on the morning of Saturday, and did not start it until after six o'clock on the following Monday morning.

Answer.—The message should have been sent the same evening. It may, however, have been stipulated in the case presented that delivery on Monday morning would be satisfactory. If not, it should have been sent the same evening and delivered next morning.

Does Rule 245 include messages that are received for transmission?

Answer.—We know of no rule 245.

IN absence of manager to dinner, a boy leaves a message for transmission, signed by unknown parties. Manager sends message ten minutes afterwards, collect. Parties addressed refuse to pay. Says it is too late to be of any use. Receiving office sends back to collect at originating office. Must manager pay for such message when sender cannot be found, or should manager not send such message? Please answer through JOURNAL. MC.

Answer.—The message should not have been sent. It was also against the rules to send such a message collect.

PLEASE say in next JOURNAL if, in computing tariff on Reds where regular rate ends with the unit 5, if we make it 6 and divide, or add 5 and make it 0 and divide? For instance, full rate, 1.25, is 63 or 65 the half rate where there are ten words or less?

MANAGER.

Answer.—63.

MARRIED.

BURROWS—REICHELDERFER.—October 15th, 1873, at the residence of the bride's parents, Lima, Ohio, Thomas W. Burrows, train despatcher C. C. C. & I. Railway, Cleveland, O., and Miss Clara E., eldest daughter of Levi Reichelderfer, Esq.

HATCH—CHANDLER.—At Gloucester, Mass., Oct. 11th, 1873, by Rev. Minot G. Gage, E. F. Hatch, manager W. U. Telegraph office, Gloucester, Mass., to Miss Lydia N. Chandler of Boston.

FIGHER—GUYMON.—At the residence of the bride's parents, at Greenfield, Ind., on the 24th of Sept., Mr. William Figher, operator W. U. office New Albany, Ind., to Miss Pet Guymon, of Greenfield, Ind.

DIED.

FARRELL.—In Virginia, Nevada, October 14th, Clarence Albert, infant son of James F. Farrell of W. U. Tel.

WOOD.—In Fort Plain, N. Y., of typhoid fever, on Thursday, Oct. 2, Gezena W., wife of George C. Wood, manager W. U. Telegraph office, aged 29 years, 2 months and 14 days.

BORN.

BUSH.—At Franklin, La., Oct. 13th, 1873, to W. T. Bush, manager W. U. Telegraph office, a son.

CAMPBELL.—At Farmington, West Va., Oct. 1st, 1873, to W. W. Campbell, a son.

RUNYAN.—To C. A. Runyan, manager W. U. Telgraph office at Canandaigua, N. Y., a son.

STRAUS.—At St. Helena, Cal., Oct. 10, to Eugene A. Straus, Manager W. U. Tel. Co., a son.

YOUNG.—At St. Louis, Mo., Oct. 18th, to W. A. Young, chief operator, Gen. Supt. office of St. L., K. C. & U. R. W. Co., a daughter.

THE GALVANOMETER AND ITS USES.

New York: D. Van Nostrand.

A handsome and convenient manual for electricians and students bearing the above title has just been published by D. Van Nostrand, 23 Murray St., New York. C. H. Haskins, the author, is well known as an experienced telegraph superintendent.

A thoroughly practical book by a thoroughly practical man, is always a welcome addition to the literature of any art or profession. More especially is it so when it comes in such a tasteful and handy form as the book before us. Mr. Haskins is unusually well qualified for the task he has undertaken, and he has performed his work in a manner which will earn him the hearty thanks of every working electrician.

The book is divided into three parts. The first is chiefly of an explanatory character, treating of the laws which govern the action of the electric current and their application to the operation of the telegraph and other cognate matters. The second part is devoted entirely to a description of the different galvanometers and other arrangements for electrical measurement, and an explanation of their use; while the third part comprises a large number of methods and formulæ for all kinds of tests and measurements, together with a large number of useful tables.

We find much to commend in the method in which Mr. Haskins has performed the difficult task of explaining the fundamental principles of electrical science in a manner to be understood without difficulty by the average telegraph operator. For example, we have never seen so clear a definition of electromotive force as he has given on page 8. He says: "The power which a cell of battery possesses of causing the transfer of its current from one place to another is its *electromotive force*. In other words, the electromotive force of a current is its power of overcoming resistance—its energy. To use a familiar comparison, electromotive force is to a current what pressure is to steam." If space permitted, we would be glad to quote other equally apt explanations of technical terms, some of which have long been a stumbling block to the student. In the second part both the Bradley and Gaugain tangent galvanometer are described, with instructions for their use. The portion relating to this useful instrument might with advantage have been made more full and comprehensive. The tangent galvanometer, as an instrument of measurement in ordinary telegraph work, is rapidly growing in favor, and it will, we think, in future be almost the only instrument used for this purpose. During the time a single wire is being tested by the differential method, an expert operator will go over a dozen wires with a tangent instrument, register the deflections, and then work them out, if necessary, at leisure. In a large office where the wires are needed every minute this is a matter of great importance. Of course, the more accurate instruments and methods come in play oftentimes in locating a cross or ground, but even in such cases nearly as good work may be done with the tangent in many cases. Clark's beautiful method of taking the internal resistance of a battery by a differential tangent instrument ought to have found a place in Mr. Haskin's book. Nearly all the methods given in the standard works on telegraphy have been brought together, and we notice several new and useful ones by Sargent, Pope, the author, and others, which add greatly to the value of the work. In fact, with this pocket companion the electrical engineer is armed and equipped to meet almost any question likely to arise in the ordinary course of his work.

Critics are nothing if not critical, therefore we shall take the liberty to point out one or two places where there is room for some little improvement. On page 7 we read that "the resistance of any iron wire per mile is found by dividing 360,000 by the square of its diameter. The quotient will be in ohms at 60 deg. Fahrenheit." As there is not the remotest hint in what terms the said diameter is to be expressed, the directions are calculated to muddle the mind of an unsuspecting youth. He might figure out that the resistance of a wire, two inches in diameter, was 90,000 ohms per mile, which may account for that astounding assertion, in a recent issue of a contemporary, in reference to "wires of all diameters, from one to two hundred miles, which electricians will find very convenient for many purposes." It will be observed that 360,000, divided by the square of 200 miles, would give 9 ohms per mile—certainly a "very convenient" wire—and thus he seems to have been led into error. If, however, the reader will turn to page 46, he will find a more rational explanation, and learn that the diameter is to be taken in thousandths of an inch or *mils* (not miles). In the directions for taking the internal resistance of a battery, on page 34, it should have been stated that the readings are to be reduced to sines or tangents, as the case may be, when the deflection exceeds 15°.

We cannot close our notice of this book without saying a good word for the publisher. Everything that clear types, good presswork and paper and excellent binding can do to add to the attractiveness of the work has been done. With a few blank leaves for memoranda and manuscript formulæ—every electrician has one or two pet ones of his own—a pocket for loose papers and a place to stick a pencil, all of which Mr. Van Nostrand will no doubt add as soon as he reads this notice, there would be very little to ask for in the way of a telegraphic engineer's pocketbook, that this work would not supply.

The cable steamer Robert Lowe arrived at Halifax, N. S., from Cape Formentine, having successfully laid the new cable between Prince Edward Island and the mainland on the 11th. The shore end was landed at Cape Traverse on the 8th, and the paying out was commenced next morning. The steamer reached Cape Formentine the same evening, but in consequence of rough weather was unable to land until the 11th.

The cable steamer Robert Lowe, October 21st, commenced at Halifax, N. S., taking on board a new cable, to be laid between Cape Breton and Newfoundland.

In carrying out plans for giving storm warnings to sea-going vessels, the Signal Office has found it necessary to make telegraphic connections with various life-saving stations along the Atlantic coast, and is building lines for that purpose. From the station at Peck's Beach, N. J., a line 10 miles long has been built to Seaville, where it connects with the Western Union. A construction party is now engaged on a line from Sandy Hook, which is to extend 50 miles southward to Squan and Barnegat. A line from Rockport, Mass., to Cape Ann, two miles long, and another from Norfolk to Cape Hatteras, 137 miles, is soon to be built. The telegraphing at these new stations will be done by soldiers instructed in telegraphy at Fort Whipple. The Signal Office has adopted the new Kenosha insulators.

J. T. Webber says, "Stop my paper; I get one from my supt." Now, Mr. Webber, where is thine abode? otherwise, where hangest thou out thy shingle? that is, where do you live? Please read our article on the "toil of carelessness."

ASSESSMENTS 49, 50, 51, 52.

15, 21, 46, 59, 64, 67, 76, 77, 86, 91, 113, 133, 140, 145, 157, 179, 208, 211, 245, 301, 342, 349, 352, 367, 380, 383, 385, 464, 510, 546, 567, 564, 615, 656, 685, 715, 721, 741, 742, 776, 797, 821, 886, 915, 916, 917, 923, 952, 1039, 1056, 1088, 1090, 1126, 1147, 1148, 1175, 1183, 1199, 1232, 1245, 1252, 1300, 1306, 1336, 1356, 1357, 1371, 1394, 1398, 1429, 1489, 1550, 1552, 1568, 1571, 1589, 1590, 1658, 1678, 1680, 1695, 1697, 1698, 1705, 1735, 1809, 1881, 1894, 1907, 1919, 1944, 1950, 1970, 2021, 2029, 2030, 2043, 2049, 2057, 2069, 2073, 2086, 2097, 2100, 2103, 2114, 2120, 2121, 2126, 2133, 2138.

The annual meeting of the Association will be held at 145 Broadway, New York, at 7:30 P. M., November 5. Two of the agents have signified their intention to be present, and others are expected.

It is felt that this meeting is of unusual importance, and it is exceedingly desirable that members at a distance should have a voice in its proceedings. We have received and disbursed about $20,000 during the past year, giving our organ zation a claim upon the body of the telegraghers throughout the country which is worthy of their consideration. The New York members have hitherto turned out in force at the annual meetings, and we hope members from a distance will also feel the duty of their being represented this time.

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, NOVEMBER 1, 1873.

BREACH OF TRUST.

It is now twenty-eight years since the telegraph commenced its mission in America. During all that time scarcely a charge can be sustained of its infidelity to the hundreds of thousands who have used it. The character of its work so appeals to honor, and so impresses with the idea of a sacred trust that telegraph operators all through the land have been faithful. This has sometimes been carried so far that an operator has been known to burn a message rather than expose it, even in a court of justice. This prevalent fidelity has been remarkable. There is a deep philosophy in it. It proves that to make men faithful they must be trusted. The exceptions only prove its truth. The public has trusted the telegraph, and its confidence has been honored. It has made a typal character. The average American operator will never divulge a secret committed to him. His very business educates him in honor.

It is therefore with much pain that we have to record the summary dismissal of A. C. Barker and W. D. Linton, of Omaha, for delivering a copy of an important political message, and a reply thereto, into the hands of Mr. E. Rosewater, Editor of the *Omaha Bee*. We give the facts below. We wish as summary a punishment could be meted out to the Editor who accepted, and, perhaps, paid for the stealing of the intercepted despatches. It is not the first time the game of bribery of telegraph men has been tried The editorial chairs have many blacklegs in them, who have prices for violated honor always ready. This Rosewater may be one of them. He bears on his stern post the marks of discharge from a business for which he was unfit.

CHICAGO, Oct. 14th, 1873.

Hon. WM. ORTON, President.

Dear Sir: This morning's *Tribune* in this city had the following "special" from Omaha:

AN ATTEMPT TO INFLUENCE THE VOTES OF WORKMEN ON THE UNION PACIFIC RAILROAD.

Special Dispatch to the Chicago Tribune.

OMAHA, Oct. 13.—A confidential dispatch was sent this forenoon, from this city to Denver, by the Western Union Telegraph, from Hon. O. I. Poppleton, attorney of the Union Pacific, to S. H. H. Clarke, Assistant-Superintendent, in which Mr. Poppleton asks Mr. Clarke for his influence on the men in the railroad shops to elect Henry Greece, the People's candidate for Sheriff. An evening paper has published the dispatch. How it obtained it is a mystery. There is great excitement over the election.

After reading it, I telegraphed Manager Lehmer, asking particulars.

I enclose copy of his reply, and my instructions. Rosewater, Editor of the *Omaha Bee*, was, for many years, in the employ of our Company, and was discharged from our Omaha office. He is capable of doing very mean things, and I should not be surprised if he bribed the two operators to give him information of matter passing through our office.

Respectfully yours,

ANSON STAGER,
General Superintendent.

MANAGER LEHMER'S REPORT.

OMAHA, Nebraska, Oct. 14th, 1873.

Yesterday a dispatch was handed in to us from Hon. O. I. Poppleton to Clark & Kimball, at Denver, of great political import to the people here. About three or four o'clock the person who handed it in came to me and said some one had made it public, and accused the employés of this office of having done so. Not knowing anything to warrant the accusations, I declined to believe it, but took immediate steps to ferret it out. From an affidavit made by E. Rosewater, Editor of the *Omaha Bee*, and published in the morning *Republican*, I was convinced it was sent out by some one connected with this office, as also a reply to the message. I called the employés together, and asked the man or men implicated to step out. An operator, named A. C. Barker, acknowledged that he was responsible for it. I discharged him, of course. I then asked him to make an affidavit, which would settle the matter. He did so. He says that he did take the message from this office to the office of the *Omaha Bee*, and gave the same to Mr. E. Rosewater, Editor of said paper. He further says, that he took said dispatch and delivered it to said Rosewater on his own responsibility, and without the knowledge of Frank Lehmer, manager of said company, or of any other official of said company. I asked him if he couldn't say without the knowledge of any one else. He said he couldn't do that, as others were implicated. I came back to the office, and operator W. D. Linton came to me, said he could not see Barker go alone, and that he was implicated also. After his discharge I got him to make the following affidavit, which is in proper form and acknowledged. "That affiant knew at the time the telegram signed by A. J. Poppleton, and addressed to S. H. H. Clark and T. L. Kimball, at Denver, was received, that A. C. Barker purposed to take said telegram, and to show the same to E. Rosewater, Editor of *Omaha Daily Bee*; that affiant was cognizant of all that was done touching said telegram, as shown by the affidavit made this day by said Barker in his behalf; and further says, that no other person or persons connected with said company, in their office at Omaha, as an officer or employé of said company, knew anything about the said matter, except affiant and the said Barker." Now the answer to this message also got out. I staid here till eleven thirty last night, to watch out for any further disclosures, but saw none. The *Republican*, however, did have the answer, and say they got it from Rosewater. I got Linton to make affidavit, willingly, in fact he offered to do it, that on last night, about twelve o'clock, he gained possession of the "press" copy of the answer, and with Barker delivered it to certain parties whom he declined to make known, and this was done without the knowledge of any one but those two. Rosewater told me, this morning, that he would publish an article of exoneration, so far as myself and others were concerned, but would not tell me who gave him the message. These men I have had every confidence in, and am perfectly astonished at their action. They are willing to do more than this to clear the company and its employés, if desired. I have been to see Mr. Poppleton, who is most seriously affected by this, and he has destroyed his complaint he had intended to send East, and will take no action in the matter. I respectfully ask instructions. Our friends say we should publish these affidavits, and a statement to the effect that the men were held in high esteem and confidence; that they have been discharged, and cannot be allowed ever to work for the W. U. Telegraph Company again.

F. LEHMER.

To this Gen. Stager sent the following reply:

Frank Lehmer, Manager, Omaha:

Consult able lawyer at once, and if there is any punishment under laws of Nebraska for divulging contents of telegraph messages, prosecute these parties to full extent of law. If Rosewater is implicated, follow him as well. Follow advice of counsel as to publication. Advise me of result of interview with lawyer.

ANSON STAGER.

MR. LEHMER'S REPLY.

OMAHA, 14th.

A. Stager, Gen'l Supt.:

Consulted with Hon. J. M. Woolworth. A careful examination shows no statute whatever bearing on the case, and advises publication of the affidavits and the following card: Answer quick if there are any changes recommended.

OFFICE OF THE WESTERN UNION TELEGRAPH COMPANY,
OMAHA, October 14th.

To the Public:

The publication, in newspapers, in this city, of private dispatches sent over the wires of this Company, entitle the public to a full explanation. The most emphatic and explicit orders are given to every employé to treat as most sacredly confidential, every message committed to us. Every effort is made by all persons in charge of the business to secure the utmost secrecy in connection with it. The young men, whose affidavits are published herewith, have been in the employ of this Company for several years. They have never been guilty of such offence before, and have been always considered worthy of the fullest confidence. I had not the slightest reason to suppose they were not perfectly trustworthy in the line of their profession. Under the direction of Mr. Stager, the General Superintendent, I have consulted counsel to learn if our laws provides any punishment for this offence, and am advised that they do not. If they did, these young men should be punished to the fullest extent of the law, in order to vindicate the rights of the public and of this Company. They have been discharged from our service, and can never obtain, anywhere, any employment from this Company, and no other telegraph company will dare to trust them as its employés. This is all the punishment which can be inflicted on them. It destroys their occupation, and is, perhaps, enough. This action has been summary as it is severe. It may prevent others from committing the same offence, if anything were necessary. We assure the public that the utmost vigilance will be practiced by all employés of this Company to secure to all persons entrusting it with messages, that sacred confidence to which they are entitled, and we believe no similar violation of it hereafter need be feared.

FRANK LEHMER.

Frank Lehmer:

Your card is approved. I suggest you add the following: "This case is remarkable, as being the only instance known to the Company where operators have betrayed its confidence."

ANSON STAGER.

We trust to be long spared from a similar record. It is the first we have ever made. Let added care be taken to protect the business from a like dishonor. Every man's reputation is involved in it. Let it be known that telegraph men can be bought, and the whole system is shadowed, and the name of operator tainted with shame. Yet all will feel, as they read the prompt and frank acknowledgment of the men who have thus erred, a wish that some road to restoration was open. We share in this. We believe in the forgiveness of sins. Here, however, we acknowledge that dismissal must, and ought to be perpetual. The offence is too fundamental. All rose water is out of place in such a case. We wish, with a fervor which our boots approve, that ROSEWATER could feel the universal kick which ten thousand toes stiffen to accord him as they read this article.

Digitized by Google

THE TOIL OF CARELESSNESS.

We believe there is a vast amount of useless sweat in this sweating world of ours. Men sweat over their mistakes instead of rectifying them, sweat over fancied injuries instead of braving them, sweat over sorrows which never come, and impose their sweat on others by barking at them their many-tongued complaints in rhetoric as irritating as incomprehensible. That there is a vast amount of anxiety and distrust caused by telegraphic correspondence there can be no doubt. In the very nature of things this must be so. Questions are asked which cannot be answered. Parties are addressed who are absent. Orders are given which cannot be filled. Messages are sent to homes where they simply create alarm or curiosity and bring no response. Many find eternal rest in some subordinate's pocket. The sweat and anger over telegraphic correspondence is no doubt fearful. Especially is this so when, to cram a message into ten words, the sense is so obscure as to make reply hazardous, or so carelessly written as to invite error. We honestly believe that half the fume and fret of this life is the result of want of care and particularity in performing daily duties.

Here is, for example, a man who sends to the Chief Executive officer of the Western Union Telegraph Company a complaint of overcharge on a message sent from Adrian to Ontario. His letter is dated Adrian. Whether his Adrian is in Michigan or New York or Illinois, or his Ontario in Canada or Ohio or New York, nobody knows. Yet carelessness in omitting full date imposes a useless complaint on a burdened officer, who will be sworn at because he does not and cannot reply, causes a half dozen computations in endeavoring to track out the wrong, and imposes upon us by being finally hung on our hooks to shoot at. No man should ever write a note to his friend without a clear date. Nothing should be taken for granted which can be easily and clearly expressed. For this want of exactness in work and in thought, in the composition of messages and in their address, in the statement of wants and the performance of labor, a vast amount of toil is added to the burdens of this toiling earth. How many thousands of messages it causes to pass unpaid for over those burdened wires we dare not estimate.

The JOURNAL has now assumed proportions which, as was well remarked by an English Journal not long ago, renders its cost utterly inadequate and ridiculous. With the opening volume, which will commence with the issue of January 1, 1874, the value of the JOURNAL will be still more enhanced. It will be printed on fine calendered paper, so as to give clearness of impression to its illustrations, and general beauty to its typography. Its matter will be more carefully select and yet varied. The odor of the shop will be less strong. The hand will not be always on the key. Yet the JOURNAL will be not the less true to its mission, truer to it perhaps than ever before. The terms will probably be changed from one to two dollars per annum. Until these terms are decided, subscriptions beyond the close of the present volume, December 15, will be declined.

H. M. BRICKETT, of Lowell, Mass., has sent us two dollars in answer to our invitation for aid to the Insurance Association by non-members. There are 4,999 more to hear from.

AT a special meeting of the Board of Directors of the Gold and Stock Telegraph Company, held at the office of the company in this city, on Monday, Oct. 27, Geo. B. Prescott was elected Vice-President.

THE London *Money Market Review* says: "The immense value of certain and instantaneous communication between this country and America has been illustrated by the crisis which has taken place in the United States. No sooner is the need for gold manifested in New York, than advices of its shipment from England reach that city, and the intensity of the panic becomes mitigated. It is also quite impossible to over-rate the advantage which European merchants have received in having uninterrupted and hourly intelligence of the facts which have occurred during these critical times."

When a great commercial panic occurs, and hundreds of excited men are seen flocking to the telegraph offices of the country with despatches for transmission, men say, "These are good times for the telegraph company." We have heard intelligent men claiming this as a feature which enhances the value of the telegraph in comparison with other property. It is a delusion. It is a mere temporary enlargement of its business, to be followed by the quiescence which succeeds all such excitements. Panics are as unfavorable to telegraphs as to all other pursuits. The healthier and more regular the condition of general commerce, so more healthily is the business of the telegraph enlarged. The excitement of the panic week leaves to-day many a wire partially employed.

The London *Railway News* thus speaks of the late George Saward, Secretary of the Atlantic Telegraph Company, whose death occurred at his residence in Camberwell, England, September 28th: "It is impossible, in speaking of the private character of Mr. Saward and of his public services, to refrain from the language of panegyric—they are not to be spoken of but with admiration and praise. His intimate friends have to mourn the loss of one whose refined and cultured tastes, whose polished manners, and whose unswerving integrity caused him to be admired and respected by all those with whom he was brought into contact, whether in business or in social intercourse." His message announcing the completion of telegraphic intercourse between Europe and America, the first prospectus of the Atlantic Cable Company having been prepared by him and much of its capital raised by his personal influence, shows the man: "August 17, 1858. Europe and America are united by telegraph! Glory to God in the highest, and on earth peace, good will towards men."

It would appear that although Mr. Saward was largely instrumental in the success of the Atlantic telegraph, he shared to a very limited extent in its substantial honors or rewards.

(*For Tariff Circular see page* 362.)

LETTER FROM MR. ORTON

MISSTATEMENTS CORRECTED.

NEW YORK. Oct. 23, 1873.

TO THE EDITOR OF THE HERALD:—

The editorial of the *Herald* of Sunday, October 19, headed "The Postal Telegraph," &c., contains certain erroneous statements, and is otherwise liable to convey erroneous impressions concerning the business of the Western Union Telegraph Company, which I ask permission to correct:—

First.—The average charge per message was sixty-one cents, as stated in the annual report, and not sixty-four and a half cents, as given by the *Herald*. The explanation of the apparent discrepancy is found in the fact that the gross receipts of the Company include moneys derived from other sources than from tolls on messages.

Second.—The statement that "the working expenses of the European lines, owned and operated by the government, average only forty per cent. of the gross receipts," is still more erroneous. The telegraph is operated at a loss by nearly every government in Europe, and the aggregate loss is several millions per annum, which is paid by taxation. In no case are the expenses less than eighty per cent. of the receipts. The average cost per message in Europe to the governments which carry on the business is greater than the average charge of the companies doing the business in the United States.

Third.—The statement that "it is admitted that the lines owned by the Western Union could be duplicated with the best English wire, the best instruments now in use, and the best poles, for $12,000,000," is erroneous, so far as the admission of any competent authority is concerned. Such a statement would be grossly inaccurate by whomsoever made. The annual report to which reference is made by the *Herald*, shows the acquisition of new property by the Western Union Company during the last seven years which cost over $13,000,000. The Western Union Company now own considerably more telegraph property than that for which the British Government has already paid over $40,000,000, gold, and an estimate of Sir Frank Ives Scudamore, now before me, states the probable cost of their telegraph property on the 31st of March, 1875, at more than $50,000,000, gold. They will not then have as great an extent of poles and wires as the Western Union now own.

Fourth.—"The stock of the Western Union is" not "watered up to three and a half times the real value of the plant." It did contain some "water," but I have already shown that over $13,000,000 has been squeezed out in seven years, and when you recall the fact that thousands of miles of line have been acquired at a small fraction of the cost to the original owners, and that millions have been contributed by railway companies to secure connection and the extension of lines upon their roads, it will be seen that the present capital of the company is not greatly in excess of, if it exceeds at all, the sum which was originally expended to produce the property.

Fifth.—The Western Union has paid no dividends in several years. What difference does it make, then, whether its lines cost $10,000,000 or $40,000,000, so far as the cost of sending messages is concerned. "One-half the present rates" would not pay the cost for operators, messengers, stationery and battery, to say nothing of maintenance, rents and interest on capital.

Sixth.—The increase of sixteen per cent. in the number of messages in 1873 over 1872 is erroneously attributed to reductions of the tariff. The only re-

Digitized by Google

duction made was "the abrogation of all rates over $2 50," and this did not take effect till February 1, 1873, and was, therefore, in force but five months of the year, which ended June 30, 1873. The other and greater reduction referred to went into effect July 1, 1873, the beginning of the present fiscal year

Seventh.—The new "square rates" are, with but few exceptions, the same as the former "special rates" established upon competing routes. The exceptions are the rates between Boston and Washington and intermediate stations. The new rates are uniform for like distances in the Eastern, Middle, Southern and Western States.

Eighth.—The *Herald* is, probably, correct in assuming that further reductions will not be made by the companies now doing the business for some time to come. The average message rate in the United States since July 1 is but fifty-five cents, which is five to six cents below the average in Europe, where the cost of telegraph material and the wages of operators are thirty to fifty per cent. less than here. More than a year ago France increased her rates twenty per cent. on one class of messages and forty per cent. on another, the latter increase being on rates which yielded over sixty per cent. of her telegraphic receipts; and yet the increase in the number of messages during the year succeeding this increase of rates was greater than during any one of several preceding years. It will not be claimed that the increase of rates caused the increase in messages, but this fact does appear—viz., that the natural growth of the business was not sensibly retarded by a considerable increase of rates.

Ninth.—The phrase "the best English wire, the best instruments, and the best poles," is liable to be construed to mean that the poles, wire and instruments of the European lines are superior in quality and working capacity to those of the Western Union. Such a construction would not accord with the facts. A very large majority of the poles used in the United States are superior to those in use in Europe. As to wire, the Western Union have been using of the "best English" 10,000 miles per annum for several years past. It is proper to say, however, that wire is now made by several parties in the United States of a quality equal to the best English, and the reasons why we use the latter at all are—(1) it is not always possible to procure domestic wire in sufficient quantities to supply our wants, and (2) we are generally able to buy English wire a little cheaper than American, notwithstanding the duty of about sixty per cent. ad-valorem. As regards instruments, those of American manufacture are superior in efficiency to the more cumbersome and more expensive apparatus used abroad. Another fact is worthy of mention in this connection. American operators using American instruments perform much more telegraphic work in the same time on the lines in the United States than is performed by the same number of operators in Europe. The telegraph office in London employs more than three times as many clerks and operators as are employed by the Western Union Company in New York to handle about the same number of messages daily.

The relations of the telegraph to the public are so important, and with the press are so intimate, as to justify the expectation that the press will not give currency to erroneous statements concerning the telegraph which may prejudice the latter in the public mind. The facts hereinbefore stated do not rest merely upon my assertion. They are completely established by the official reports of the governments by which the business is carried on abroad and of the companies conducting it in the United States, and to deny them in the face of the evidence which is now accessible would seem to imply an indisposition to do justice to the American telegraphic system, which cannot actuate the conductors of so successful a specimen of American enterprise as the *New York Herald*. Very respectfully,

WILLIAM ORTON.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 BROADWAY, NEW YORK,
NOVEMBER 1, 1873.

To all Offices on W. U. Lines:

GENERAL INFORMATION.

The following changes and additions have been made since the date of the last Circular:

The attention of offices recently taken from "SPECIAL SHEET A" by the notices in JOURNALS dated September 1st and 15th, and October 1st and 15th, is called to the following notices:

When computing tariff on messages to Hastings Lake City, Minneapolis, Red Wing, St. Anthony St. Paul, Stillwater, Wabasha and Winona, Minn. and La Crosse and Prescott, Wis., offices of the N. W. Tel. Co. take the rates printed in the tariff book as "Tariff for other lines" instead of 55 and 4, as heretofore.

When computing tariff to points whose rates are made by adding to any of the above-named offices, as, for example, the points in Minnesota, given in JOURNAL of April 1st, 1873, add to the printed rate to such office, instead of adding to 55 and 4.

Offices in the West, having "*Sheet C*," will charge to offices of the N. W. Tel. Co., as that sheet directs.

Half-rate messages will still be taken for and received from the offices of the N. W. Tel. Co., named above.

St. Marks, Fla., re-opened.
Acworth, Ga., closed.
Mansfield, Ill., closed.
Postville, Iowa, is now a W. U. office, square 366; check direct.
Cummins, Ks., closed.
Chanute, Ks., changed to New Chicago.
Riga, Mich., re-opened.
Business for Morenci, Mich., may be sent via Detroit, Mich.; "tariff for Other Lines" same as via Toledo, 25 and 2
Austin, Minn., is now a W. U. office, square 406; check direct.
Sardis, Miss., re-opened.
Messages for West Wareham, Mass., should be sent and checked to Tremont, Mass. They are one and the same place.
Business for Fayette, Fulton Co., O., may be sent via Detroit, Mich.; "tariff for Other Lines" 25 and 2, same as via Toledo, O.
Liverpool, Pa., closed.
The tariff to Paxton House, Pa., is 10 cents more than the rate to Oil City, Pa.; check Oil City. (See "Exceptions" in last JOURNAL.)
Birdsboro, Pa., re-opened, square 59.
Antwerp City, Pa., closed.
The P. O. A. of Everson, Pa., is Fountain Mills, Fayette Co., Pa.
Bay Verte, P. E. I., closed.
Woodburn, O., closed.
Calvert, Texas, re-opened.
Englewood, Texas, closed.
Hallville, " re-opened.
Palmer, " closed.
Healing Springs, Va., closed.
Warm Springs, Va., closed.

* Wilton,	"	75	5	307	" "

The delivery charge to the Insane Asylum near Milledgeville, and to Midway, Ga., is 50 cents instead of 5 cents., as published in last JOURNAL.

SPECIAL RATE OFFICES.

The tariff to Birdsboro, Pa., is 25 cents more than special rate to Philadelphia; square rate not to be increased.

ATLANTIC CABLE BUSINESS.

We are informed that the Cable between Singapore and Hong Kong is now repaired. Direct telegraph communication to China and Japan is again established.

The Cable between Falmouth and Lisbon is broken. Business will be sent via other routes, rates unchanged.

The Continental rate to German Alsace and Lorraine is $1.50 from France instead of $1.10 as heretofore.

CUBA CABLE BUSINESS.

Communication by cable between Batabano and Santiago, in Cuba, is interrupted. Messages for the latter point will be mailed at Batabano, via steamers leaving two or three times per week. Messages for places beyond Santiago will be sent by telegraph and mail to Santiago, from which point they will be forwarded to destination.

The Cable between Jamaica and Aspinwall is now open for business. Tariff in addition to the rate to Kingston, Jamaica, five dollars, gold, for ten words, and fifty cents for each additional word.

Messages to Aspinwall by this route must have the words "Care of Nunes" inserted as part of the address.

WILLIAM ORTON,
President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Oct. 28th, 1873.

On November 1st, Peru, Ind., office will be transferred from J. J. S. Wilson's district to J. F. Wallick's district.

G. H. MUMFORD, *Vice Pres't.*

The annual meeting of the Telegraphers' Mutual Life Insurance Association, to be held at 7 P. M., Nov. 5th, will be an important one. The question of limiting payments to $1,000 at death, and under what circumstances payments shall be made from reserved funds without calling for assessment, will be discussed. Some limitation seems imperative. The last assessment of four dollars proves this. It comes hard on many. Means should be taken at once to keep the Association above the fear of disintegration by reason of excessive assessments. By limiting payments to $1,000 and with a membership of 1,500, eight assessments would provide for twelve deaths. We hope action will be taken in this matter. The Association should be kept from peril. Its terms should be such that none need fear to join it. A large and interesting meeting is hoped for. The place of meeting is at 145 Broadway, N.Y.

RED STAR LINE.

ANTWERP SERVICE.

APPOINTED TO CARRY THE BELGIAN AND UNITED STATES MAILS.

		From Antwerp.	From Philad'a.
"VADERLAND," Captain Vander Heyden,	2800 tons.	Nov. 12.	Oct. 22.
"RYDAL HALL," Captain Collin,	2114 tons.	Oct. 11.	Nov. 5.
"NEDERLAND," Captain H. W. James,	3000 tons.	Oct. 25.	Nov. 22.
"SWITZERLAND," Captain ——,	3000 tons.	Building.	

PRICES OF PASSAGE:

Cabin.....$100 gold.
Steerage.....35 currency.
Prepaid Certificates, $36 currency.

LIVERPOOL SERVICE.

	Tons.	Master.	From Liverp'l.	From Philad'a.
"ABBOTSFORD,".....	2588.	Findlay.	Oct. 29.	Nov. 20.
"KENILWORTH,".....	2588.	Putt.	Nov. 12.	Oct. 23.

PRICES OF PASSAGE:

Cabin.....$100 gold.
Steerage.....30 currency.
Prepaid Certificates, $32 currency.

Tickets will be sold here at lowest rates, good from Antwerp and Liverpool to all interior points in the United States, *via* the Pennsylvania Railroad and its connections, thus affording parties in this country a convenient and cheap opportunity of sending for their friends in Europe.

THE RED STAR LINE will give special attention to the comfort of steerage passengers; comfortable berths, well-ventilated sleeping apartments and good food will be furnished them.

An experienced Surgeon is attached to each vessel.

Freight will be received at all principal points in the West and South, in connection with the Pennsylvania Railroad, Southern Mail Steam-ship Company and Clyde's lines, and through Bills of Lading issued for Antwerp, Bremen, Hamburg, Havre, Amsterdam, Rotterdam, Liverpool, London, Glasgow, Belfast, Hull and Leith.

The Red Star Line docks at Philadelphia are in direct connection with the Pennsylvania Railroad, and all merchandise intended for points beyond Philadelphia can be transferred from the hold of the steamer to the cars without the expense to shippers and risk of damage by re-handling, which results from cartage.

For rates of freight and passage, and other information, apply to

PETER WRIGHT & SONS,

GENERAL AGENTS, PHILADELPHIA.

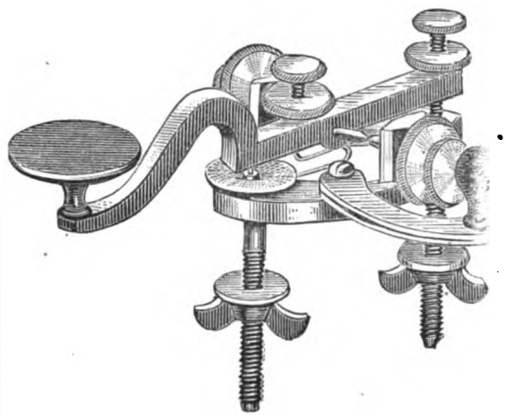
According to the account given of a hippopotamus family jar by a writer in *Land and Water*, who recently witnessed a domestic infelicity of this nature in the Zoölogical Gardens at London, nothing more extraordinary than this, in the way of a conjugal "row," could be imagined. The male and female hippopotami in the Gardens are known respectively as Obesh and Dil. Their youthful offspring, now eight months, and whose name is Guy Fawkes, was, until a few days ago, kept in the den with his mother. The family disturbance referred to above occurred when the time came for Guy Fawkes to be introduced to his father. The portcullis of old Dil's den having been raised, she and her offspring came out and marched towards Obesh, who was munching grass near by. As his wife approached him, Obesh trumpeted several times and grinned. Guy Fawkes went up to his father and began to rub his nose against the parental snout. This sort of thing lasted for two or three seconds, and suddenly old Dil rushed at Obesh, and the two gigantic beasts engaged for a few minutes in a savage fight, rearing upon their hind legs, clashing their tusks together, opening their portentous jaws, and biting at each other maliciously. Obesh was finally worsted, and was ignominiously driven into his pond, while the "old woman," with Guy Fawkes on her back, stared at him, grunting, and apparently threatening him, for three-quarters of an hour. At the expiration of that time, however, peace was declared, and the most affectionate family endearments known in the bright lexicon of hippopotami were exchanged between the now reconciled and contented trio. Obesh has, for a hippopotamus, a rather disagreeable reputation, and having been in the Gardens for twenty-three years, he is, in a measure, to the other animals what Mr. William Dorrit was to his companions of the Marshalsea.

WATTS & COMPANY,



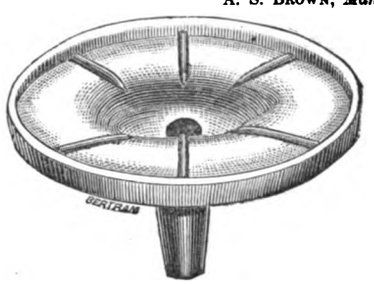
47 Holliday Street,

Baltimore, Md.,

SOLE MANUFACTURERS OF THE

PATENT CIRCUIT-CLOSER KEY,

Which has met with marked success.



Price, $5 50 plain..$7 nickel-plated.

The following is from a competent judge, written after some weeks' trial.

145 BROADWAY, NEW YORK, Sept. 22d, 1873.

DEAR SIR,—Your circuit-closing attachment on the key, left with me for trial, is pronounced by all who have used it a decided and much-needed improvement on the common form.

Respectfully,
A. S. BROWN, *Manager.*

The Best Form of Battery Insulator Offered.

SIMPLE AND PERFECT.

Made of porcelain, handsome in appearance. Occupies little more space than the cell it supports. Each cell of battery completely isolated. Leakage is reduced to the minimum by the use of it.

General Superintendent Van Horn, Southern Division W. U. Tel. Co., writes of it:

"We have now in use a thousand or fifteen hundred of your battery insulators, and expect to order many more before the close of the year.

We have never used any battery insulator that equals it in any respect. In fact, it appears to be as near perfect as we can reasonably expect, in a contrivance for that purpose."

Price 40 cents

We offer a very excellent article of Galvanized Wire, superior to any in the market. The linemen on Baltimore and Ohio R. R. say they have never seen its equal for toughness and flexibility.

Special attention given to building.

Estimates given for any amount of material for telegraph construction or extension.

SWITCHES, GALVANOMETERS, RESISTANCE COILS &c., to order.

Designs for Switch Boards for special service furnished.

SCOTT'S PATENT ANNUNCIATOR,

for Hotels and Residences.

PENSACOLA TELEGRAPH CO.

C. L. L BARON, *President.*

Baltimore, Md.,

MANUFACTURE

Telegraph and Electrical Instruments

OF EVERY DESCRIPTION.

Facilities for supplying any description of Machinery or Material equal to any in the United States.

Patented Dec. 31, 1872.

Over SIX THOUSAND cells of the Baltimore Battery in use by the Gold and Stock Telegraph Company of New York in their Private Line Department, as a form of the gravity battery, combining the valuable principles of

Economy, Cleanliness and Constancy,

"—in fact a base-burner."

F. L. POPE,
Telegrapher, July 5th, '73.

SELF-FEEDING,

No Sulphate of Copper can reach the Sulphate of Zinc Solution.

The shape of Zinc and Copper, which, with the tube, were patented December 31st, 1872, secures the largest surface with least weight of the metals. Half pound sulphate copper per month, ample supply for No. 2, or 3.

Following is one of the many letters we have from reliable telegraphers:

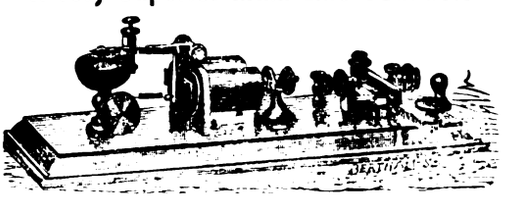
PIEDMONT, W. Va., September 28th, 1873.

Messrs. WATTS & Co.,
Baltimore, Md.

GENTLEMEN:—On January 1st, 1873, I put up 75 cells of your No. 2, Baltimore Battery, in place of 40 cells of carbon, from which two railroad wires of 100 miles each, are supplied. It has not since been taken down or cleaned, and has required no attention, except to fill the tubes with blue stone, once each month, and replenish the fluid once or twice during this period, made necessary by evaporation.

I am fully convinced, from long experience, that this is superior to any other form of the gravity battery.

It has now been in constant use for nine months, and will not need new zinc until after January next.



Respectfully,
J. G. NESBITT, *Manager.*

ORDERS FOR THIS BATTERY PROMPTLY FILLED.

A large stock constantly on hand.

No. 1 for Electro-motors, R. R. signals or similar service, $2.25
No. 2 ordinary local or Printing Telegraph main $1.75
No. 3 ordinary main $1.25

A very Superior Main Line Sounder.

Brass, $22.50. Nickel-plated, $25.00.

For wrecking purposes or temporary offices, this instrument is without a rival.

A perfect combination, handsome, good-sounding instrument.

NO LOCAL REQUIRED.

Well seasoned black walnut box, large enough for pencils, paper, plyers and office wire, in addition to the instrument, $4.

Larger size for climbers, vises, &c., $5.50.

RELAYS, SOUNDERS AND KEYS,

always on hand, plain or plated.

Our Challange Sounder is the noisest instrument made.

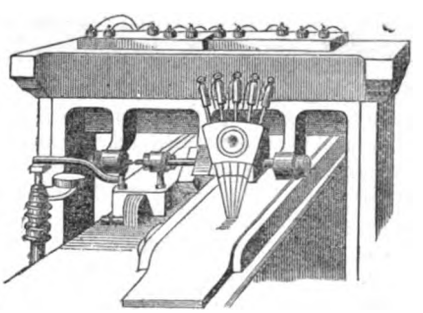
JOURNAL OF THE TELEGRAPH.



VOL. VI. NO. 24. NEW YORK, NOVEMBER 15, 1873. WHOLE NO. 145.

MAGNETISM.

Physicists find that in horse-shoe magnets the portative force increases with the time of contact of an armature. The author wished to know whether this increased magnetism would be shown by his method of induction-currents. He placed round one of the braches a loop of wire connected with a galvanometer, applied an armature of soft iron, and observed the current of demagnetization; first, when magnet and armature had been in contact only a few seconds, and next, when the contact was prolonged several hours or days. The current was always the same, and the result is thus in discord with that above stated. M. Gaugain further determined the curve of demagnetization of an electro-magnet, placing his wire loop successively at different points of the bar, and observing for each position the strength of induced current developed at the moment of interruption of the inducting current. The curve rises from the ends of the branches, reaches a maximum at a point covered by the bobbins, and then gradually falls to the heel. Thus its inclination changes sign four times throughout the length of the bar. Now, if one examines with a magnetized needle the magnetic state of an electro-magnet, one also finds that the magnetism changes sign four times. Starting from the boreal extremity, for example, the magnetism at the other side of the nearest bobbin is austral, it is zero at the centre of the bar, becomes boreal on approaching the second bobbin, and, finally, is austral beyond this bobbin at the end of the bar. This correlation is a striking one. In the case just described no armature was applied; where there is such, then, to obtain the curve of demagnetization a new series of experiments have to be made. The loop being placed successively at various points of the bar, one determines for each point the value of the detachment-current (meaning by this the current induced when the armature is detached). By means of this curve, and the curve of demagnetization obtained when no armature is applied, one may easily trace the curve of demagnetization for the case in which the armature is applied. Studying this curve, it appears that the increase of magnetism near the extremities on application of the armature is enormous; it may be 60 or 100 times the magnetism found before application. In the case of a permanent magnet, the increase on application of an armature was not more than five or six times the previous magnetism. From this difference it results that if we compare an electro-magnet and an ordinary magnet by Coulomb's method of oscillations, and the method of weights carried, we should find by the former that the electro-magnet is weaker than the magnet, and by the second that the magnet is the weaker. These results are not in contradiction; the first method measuring the magnetic intensity which exists before the application of the armature, while the carried weight depends on the magnetic state produced after the armature is applied, and, as we have seen, the modification of magnetic state by the presence of an armature is very different in electro-magnets and in magnets. M. GAUGAIN.

AUTOMATIC TELEGRAPHS—BONELLI'S CHEMICAL TELEGRAPH.

The invention of Chevalier Bonelli is for automatic transmission and the delivery of *fac similes* of the original message. The apparatus consists of a long stage or railroad on a table, on which travels a wagon, containing, on the left side of the lower half, a box of raised metal types, and on the right side of the upper half a strip of chemically prepared paper. Over the middle of the railway is a bridge, under which the wagon has to pass when transmitting or receiving a message. There are two buffers for receiving the wagon at the ends of its journeys. Just in front of the buffers, and level with the rail, is a hook, which engages with an eye at the upper end of the wagon, and holds it until a current traverses the line and releases it by means of an electro-magnet. On the left-hand side of the bridge, over the raised types, is a type-comb, consisting of five

movable teeth, insulated from each other, which are connected to the ends of five wires, going to a similar number of styles at the receiving apparatus. As the wagon, with the types looking upwards, passes underneath the type-comb, the teeth come lightly into contact with the raised portions of the types, and close the circuit whilst the contact lasts. Thus letter after letter is transmitted.

The right side of the bridge, which spans the middle of the rails, is appropriated to the reception of messages. It consists of a writing-comb, composed of five teeth, made of an alloy not liable to corrosion, insulated from each other, and pressing lightly upon the paper strip. This comb would produce, if each tooth were traversed at the same time by an electric current, five lines, something like the lines on music-paper. As, however, they are each only traversed by a current during the time some portion of a type is underneath the corresponding tooth of the type-comb at the sending station, they can only give lines at such intervals and of such length as are determined by the form of the type.

With this system, any deviation from synchronism is of small importance, as the difference in one way or the other will only make the letters printed either a little narrower or broader than the types used in sending, and in this consists the advantage of the Bonelli arrangement over those of Bain and Bakewell.

A very high rate of speed is, of course, attainable by a system of this character, but this advantage is more than neutralized, owing to the fact that five wires are required in its operation, and that before transmission it is necessary to set the message in type.

The paper intended for receiving permanent printing by the Bonelli instrument, for distribution to the public, is prepared by being saturated in a solution of nitrate of manganese, which yields, under the action of the current, a light, brown-colored precipitate. That which is termed "fugitive printing," as for press work, by which the impressions are not necessarily of a permanent character, is done with paper prepared with a solution of iodide of potassium, which gives letters, at first, an iodine character, but which, in course of time, lose their intensity and wholly fade away.

THE HEROES OF SHREVEPORT.

LETTER OF SUPERINTENDENT BAKER.

SUPERINTENDENT'S OFFICE, SIXTH DISTRICT,
LITTLE ROCK, Oct. 9th, 1873.

JOHN VAN HORNE, Esq., Gen'l Supt., Louisville, Ky.:

Dear Sir: I telegraphed you yesterday of the death of Alfred Saville, manager at Shreveport, La., of yellow fever, making the fourth victim of the disease among the employés of this Company at that place within less than one month's time.

On the 1st of September our force at Shreveport consisted of Geo. J. Rae, manager, Thomas M. Jackson, and Charles Newton, operators, G. H. Reinicke, local repairer, and Louis Lanone and Eddy Pike, messengers—six in all. On the 11th not one of them was left for duty, except one of the messengers, and the office was closed. On the 3d Mr. Newton became alarmed and resigned. The others elected to remain. On the 6th, Jackson and Reinicke were reported sick of the fever, leaving Rae alone. Heroically he stood to his lonely post, with death staring him in the face, until the 11th, when he, too, was stricken down. Jackson and Reinicke died on the 13th, Rae on the 15th. Of the messengers I could hear nothing, except that one of them, Eddie Pike, had taken the fever. On the 15th I engaged Mr. Saulsbury, operator of the Texas and Pacific R. R. Co., who had an instrument in circuit at the depot of that Company, in the edge of the town, to send and receive as many messages of an urgent character for us as his railroad duties would permit. On the 14th Mr. H. C. Davis, an acclimated operator, sent to our aid by Mr. Flanery, arrived at Shreveport, and we were enabled, partially, to resume business. On the 12th I accepted the volunteered services of Mr. Alfred Saville, and he arrived at Shreveport on the 16th, taking charge as manager. I also accepted the services of Mr. Wm. Bernard, formerly of the Cincinnati office, who arrived here *en route* to Shreveport, just in time to help us nurse and bury

Digitized by Google

Mr. John A. Conley, formerly of the Huntsville, Ala., office, whom I had employed for the Little Rock office, but who was taken sick with the yellow fever in Memphis, and arrived here with the disease upon him. He died on the 18th, thus adding one more to the list of victims in this district. Mr. B. L. Smith, who recovered from the fever this season at Pensacola, also volunteered, and was sent to Shreveport. By the 22d I once more had a force there, sufficient to transact such business as offered; but, in the meantime, the epidemic had transformed the town into a hospital. All who could had fled, reducing the population to about 4,000. Of these, 700 to 1,000 were constantly sick, and the deaths ran from twenty to forty daily. The fever was of a very malignant type, killing over sixty per cent. of those attacked. Business was generally suspended, nearly all business houses being closed. The railroad trains and stage lines were stopped, and the town almost entirely cut off from aid, save by telegraph. Fortunate it was, indeed, for the doomed place, that a few devoted men were found who were willing, at the risk of life, to keep open the doors of the Western Union Telegraph office. The Company having generously authorized free transfers of money, subscribed at points throughout the country, for the relief of the sick and destitute, and our banker, Mr. George A. Pike, agreeing to pay these transfers for us at Shrevesport, free of charge, for exchange, the telegraph wires became at once the sole means of relief. All eyes and hearts were turned upon the little band of men who so faithfully worked them amidst such danger. Electricity was the only thing that the outside world could not quarantine, and the telegraph became the sheet anchor of all those people during the fearful plague which still prevails. Until Mr. Pike's funds gave out, from accumulating at other points, we paid out transfers at the rate of over $250 per day. This was in addition to the telegraphic checks, which he and other bankers paid for the relief of the suffering, and which were sent free over our lines, without passing through the hands of our transfer agents. The lives that have been lost in our service at Shreveport were not, therefore, thrown away or uselessly sacrificed. They were lost in the noblest of battles, —that against pestilence for the relief of suffering humanity.

After the loss of so many valuable men, I hoped the epidemic would not again invade our office, but our poor fellows seemed marked for destruction. The office seemed to be infected. I was notified on the 30th that Mr. Saville had taken the fever. Doctors Choppin and Hurd, of New Orleans, and the best nurses to be found, were at once placed in attendance upon him, and his case progressed so favorably for a few days that we all were sanguine of his recovery. But the sudden change in temperature on the night of the 6th of October, when the mercury fell fifteen degrees within an hour at Shreveport, proved fatal to him, and to many others. Notwithstanding all that could be done, his physicians were compelled to announce his case hopeless on the 7th. I at once telegraphed his wife, at Grenada, Miss., of his condition, and she sent him a farewell message. I never wish to hear such another. It sounded like a wail passing over the wires. Saville received and understood that message, and said: "I want for nothing now; I am near heaven." He was attended in his last moments by the Rev. Dr. Wilkinson, who noted his last words and message to his wife. He was buried yesterday at 12.

I have forwarded copies of your message, and of Mr. Orton's, to Mrs. Saville, and to Mr. Jackson's mother, at Dalton, Ga. Mr. L'Hommedieu will forward copies to the relatives of Rae and Reinicke. We will gather such particulars of the circumstances of the relatives of those who have lost their lives in the Company's service as we can, and forward them, as Mr. Orton directs.

The fever continues to rage at Shreveport, and I dread to listen to messages coming thence to me. The present force consists of Wm. Bernard, acting manager; H. C. Davis and B. L. Smith, operators, and Thos. Logan, clerk. They show no signs of fear, but stand to their posts, each like the Roman soldier at the gate of Pompeii, but facing a more terrible foe. The Company may well hold such men in high esteem. It would be in vain to look for stronger proof of devotion to duty, or for greater sacrifices to the cause of suffering humanity, than we find in the cases of Rae, Jackson, Reinicke and Saville. There are few operators who, to-day, sitting at their instruments, if they have heard his story, cannot imagine poor George Rae, standing his five days of lonely watch, with his comrades dying around him, waiting, without relief, for yellow fever and death. There is no man who can think, without admiration, of Saville's volunteering to go into the danger, because, as he said to me, he thought "it was his duty, and as so many were running away, he wished to go to the aid of the sick and suffering," or without a tear of sympathy, of his death among strangers, and that last heart-broken message from his wife.

I would suggest that at some future time the Company cause to be placed over the remains of such of these faithful ones as may lie in the cemetery at Shreveport an enduring stone, that will mark their resting place, and tell how they lost their lives.

Yours, truly,

L. C. Baker, Sup't.

THE BEES AS ARCHITECTS.

Man is obliged to use all sorts of engines for measurement—angles, rules, plumb lines—to produce his buildings and to guide his hand; the bee executes her work immediately from her mind, without instruments or tools of any kind. "She has successfully solved a problem in higher mathematics, which the discovery of the differential calculus, a century and a half ago, alone enables us to solve at all without the greatest difficulty." "The inclination of the planes of the cells is always just, so that, if the surfaces on which she works are unequal, still the axis running through it is in the true direction, and the junction of the two axes form the angle of sixty degrees as accurately as if there were none." The manner in which she adapts her work to the requirements of the moment and the place is marvellous. In order to test their ingenuity, Huber glazed the interior of a hive, with the exception of certain bits of wood fastened on the sides. The bees cannot make their work adhere to glass, and they began to build horizontally from side to side; he interposed other plates of glass in different directions, and they curved their combs in the strangest shapes, in order to make them reach the wooden supports. He says that this proceeding denoted more than an instinct, as glass was not a substance against which bees could be warned by Nature, and that they changed the direction of the work before reaching the glass, at the distance precisely suitable for making the necessary turns, enlarging the cells on the outer side greatly, and on the inner side diminishing them proportionately. As the different insects were working on the different sides, there must have been some means of communicating the proportion to be observed, while the bottom being common to both sets of cells, the difficulty of thus regularly varying their dimensions must have been great indeed.—*Scientific American.*

ELECTRIC RAILROAD SIGNALS AT VIENNA.

Mr. Robert James Manos, M. D., reporter for the "Society of Arts" at the Vienna Exhibition, describes as follows three electric signal systems exhibited at Vienna, all by Englishmen:

Mr. Preece has sent to the Exhibition a complete set of the apparatus (4,866) he employs for the "block" system of railway signaling on the Southwestern line. The fundamental principle in this system is that trains on the same line are to be kept apart by a certain and unvariable interval of space, instead of by an uncertain and unreliable interval of time. In Mr. Preece's method the signal which opens any "blocked" section of line is made by the signalman at the advanced end where the section has to be cleared, and no signal is held to be effective and complete until it has been acknowledged by the receiver, and "repeated" back to the sender. Mr. Preece also lays great stress upon the fact that the miniature apparatus which he employs in the signalman's room, and which is the apparatus that is shown in the Exhibition, shall all have identically the same form as the instruments used for displaying the effective signals on the line. The switch in both instances is worked by the same movement of the arm. In both instances the horizontal red arm on the signal-post means the same thing. A strong and uniform association is thus established in the mind of the signalman, which becomes almost an instinct, and is never confused or disturbed in moments of emergency. It is also an important part of the arrangements that the horizontal or "danger" position of the semaphore arm is maintained by gravity, and it is the dropping of the arm that is brought about by electrical action. If any accident occurs to the electric wires, so that the transmission of the currents is arrested, all that can happen is that the danger signal remains resolutely and obstinately displayed, and that all traffic is for the time suspended. The effective parts in the instruments are of extreme simplicity. In every instance, excepting one, the movement is effected by converting a core of soft iron into a magnet when an electric current is sent through a surrounding coil. The semaphore arm is dropped by an induced magnet pulling up its weighted end. The bell is rung by an electro-magnet acting on the vertical elastic rod of its hammer. The semaphore sends back a "repetition" signal for itself to the station from which it is worked, to show how its arm is placed; and it does this by turning on a current from one or other of two distinct batteries by their negative or positive pole as required. The current, as it rings the bell, acts on a permanent magnet, hung between the poles of the electro-magnet, so that the magnet is drawn to the right or to the left as the "danger" or "clear" signal is to be recorded. The best method of working the system requires three wires between the stations; one wire to connect the bells and repetition signals of both stations, a second to connect the switch of one with the semaphore of the other, and a third to connect the semaphore of that station with the switch of the other. The advantage of this is that the currents which effect the signals are maintained so long as they have to be displayed, and lightning, electric clouds and earth currents are powerless to produce derangement. Each signal station, unless it is a terminal one, needs a double set of the four instruments; namely, bell-key, bell and repetition signal, switch and semaphore post. By a differently arranged apparatus one wire can be made to work all the signals; but the current is then a momentary and interrupted one, and other expedients have to be brought into play for obviating the occurrence of disturbance

Digitized by Google

from lightning or earth currents. The bell-key turns on its electric current by pressing the end of a flat spring, which forms one pole of the battery, into contact with a metallic pin or standard in communication with the other pole—the switch accomplishes the same thing when lying across a brass arc in one direction, but not when it is thrown fully back the other way. The brass arc, a little above the pivot of the switch handle, it will be observed, is cut through. The pivot is in communication with one pole of the battery, one-half of the interrupted arc with the other pole, and the other half with the earth. The three binding screws of the switch accomplish these three different communications. The largest semaphore instrument shown by Mr. Preece is an apparatus contrived to warn a signalman when a signal lamp that is out of the range of direct observation is extinguished. A brass arc placed above the flame of the lamp is expanded, and pushes up an elastic bar, so as to "break contact" and interrupt an electric current; when the lamp goes out, the arc cools and contracts, the bar settles back and renews contact, and an electric current is turned on to the signal room, to make a temporary magnet there pull over an index so as to show "light out" on the face of the instrument.

Mr. Harley, of Barnsbury, proposes to work the "block system" of railway signaling by a single wire, that shall have complete immunity from disturbance from lightning, electric clouds, or earth currents, and the apparatus which he employs, and which is shown by him in the Exhibition (4,842), is of an altogether novel construction in one particular. The needle which swings vertically on the dial is *not a magnet*. It is a pointer of soft iron, suspended upon a centre pivot, carrying horizontally beneath the pivot a flat soft iron ring. The ring hangs a little way beneath the pivot by a rigid connection, and when horizontal keeps the pointer vertical by its own weight. A permanent horse-shoe magnet above directs its poles towards the flat edges of the ring, and, at the same time, the ring is invested by the coils of an electric-current conveying wire. When no current is traversing the coil, the flat ring keeps horizontal, because it is pulled up equally both ways by the poles of the magnet, and is held back equally by its rigid attachment to the pivot. But when a current traverses the coil, the flat ring becomes temporarily an induced magnet, and is pulled up on one side and pushed down on the other by the opposite poles of the permanent magnet, and the pointer, at the same time, is consequently moved on the dial in the same direction. The signalman who sends a signal can turn on either a positive or a negative current by using one or other of two contact levers at discretion. As he turns on one or the other, he makes the needle traverse to the right to signify "all clear," or to the left to signify "stop." When the receiving signalman is warned by a bell that a signal is coming, he presses a knob, and so switches the current from the bell instrument to the signal instrument. In doing so, he draws back two ivory pins, which allow the needle-pointer to traverse freely to either side; and when he releases the knob, the pins start back and intercept the needle, and so fix it as a continued record. It is a distinctive attribute of this ingenious apparatus, due to the inventor of the soft iron ring and pointer, that extraneous magnetic force is absolutely powerless over its indications. While the apparatus is at work, Mr. Harley flashes a powerful magnet about it, above, below and around, in a way which would put the ordinary magnet-needle instruments of the needle-telegraph entirely out of the field, but without producing the slightest derangement in its signaling operations.

Messrs. Carr & Barlow, of Old Palace Yard, propose to dispense with the large staff of signalmen in working the block system, and to make the traveling engine which drags the train do their work. The arrangement by which they conceive this may be effected is shown in a working model. A signal instrument is placed on the engine, where it is under the eye of the driver. When the engine enters upon a distinct segment of the railway, a trigger is pressed as its bottom passes a projection on the line, and this drops a screen on the signal instrument, and shows "stop," unless a preceding train has passed out from the other end of the segment, pressed down a lever there by its wheel, and turned on a backward current of electricity; then the current is communicated to the engine signal-instrument, at the same time that the trigger is pressed, by two curved metal springs on its bottom rubbing against corresponding metal plates on the line, and two screens are dropped on the instrument, one mechanically and one electrically, and "Go on," instead of "Stop," is displayed. Midway of the block-segment a transmission instrument and galvanic battery are placed, the former on a low post near the line. Contacts are made and electrical currents formed on this instrument by a very pretty contrivance. A kind of flat brass hammer falls into a wedged-shaped interval, separating two steel faces. When the hammer is down, the current passes from one steel face to the other through it; when the hammer is up, the current is interrupted. As the engine passes abreast of the transmission instrument, it presses a lever by its wheel, drops one hammer, and establishes a backward current, and lifts the other hammer to interrupt the current coming in from the front. When the engine passes out at the far end of the block-segment, it drops again the second hammer, and re-establishes its current to give the signal "All clear."—*Railroad Gazette.*

SIGNALS AT THE GRAND CENTRAL DEPOT IN NEW YORK.

The New Haven (Conn.) *Register*, of recent date, says: "On Saturday last, at the Grand Central Depot in New York, by the kindness of station-master Franklin, we spent half an hour in the signal office of glass, at the north end of the depot, where a full view of all incoming and departing trains was obtained, and the thorough system of signalizing in force fully explained. About 150 trains leave and arrrive at this station every day, and the departure and arrival of every one is controlled by the signal officer. This officer has between thirty and forty different telegraph signals to touch, on a table at his side, and none of them are labeled. He touches one half an hour previous to the departure of an express train, another at twenty minutes previous to the departure of a way train, and the movement rings a bell in the waiting-room from which the passengers are to depart. The doors open instantaneously, and the crowd of passengers can be seen making their way for seats in the train for which they have tickets. He then touches a key which causes the engineer to back his engine into position where he can be readily ordered on to his train. At five minutes before the hour of departure he rings a bell in the waiting-room and baggage-room, notifying them not to check any more baggage and not to sell any more tickets, and when the time is up he strikes a key to close the doors, and no more passengers can enter for that train. He strikes a signal which throws up a letter, either X, for the Harlem; Z for the Hudson River; or Y, for the New York, New Haven and Hartford road, and at the same time rings a bell beside the engine, which notifies the engineer to back down. He then touches a key to ring a bell notifying the brakemen to couple on, and at the time of starting strikes a bell, and the 'All aboard' of the conductor is simultaneously heard. As soon as the train starts this officer makes a record of the departure, and immediately telegraphs to Mott Haven that such a train has left, with so many cars, and after raising signals at Fifty-third and Fifty-sixth streets, so that no incoming trains shall interfere, his duties with the outgoing train are ended.

"Of incoming trains he had also a perfect control. Whenever a train passes the junction near Mott Haven, the operator there telegraphs where it is from, how many cars, and the time it passed. At Ninety-sixth street the train strikes a signal which sets a bell ringing in the signal office, which continues until the train reaches Seventy-sixth street, and then ceases. At Sixty-first street another signal is struck which rings a bell at the signal office, which rings until the train arrives at Fifty-sixth street. If the officer in charge sees that everything is clear for the train, he allows it to run in; if otherwise, he throws out a flying signal at Fiftieth-street, which will stop the train until it is ready for the entrance to the 'Grand Central Depot.' The departure and arrival of trains so frequently, without the least delay or accident, is a marvel, and is almost wholly dependent upon the signal officer. With the present arrangement and competent officers in charge, an accident to an incoming or outgoing train is an impossibility."

TAYLOR ADAMS' GRAVE.

The Day of All Saints, set apart in commemoration of the saints to whom no special day has been assigned, is one of the most important and imposing festivals of the Catholic Church.

A clear sky, a bright sun and a gentle, bracing breeze, just cool enough to be pleasant. The crowd, hurrying along as on All Saints' Days for generations past, was large, and it began to move at an early hour in the morning, jostling each other, and filling the cars, and gathering in multitudes in the silent cities of the dead, where each could claim a loved and lost one, and silently and sorrowfully doing their work of love that told a story of a memory cherished, a voice remembered and an image shrined in the heart.

The stately mausoleum bore its tribute of flowers, and the lowly mound which it shadowed, nestling beside it, too, had its wreath.

Among the most noticeable decorations at the St. Joseph Cemetery, on Washington street, New Orleans, was the grave of the late Taylor Adams, who was so well and favorably known in connection with the Western Union Telegraph office here. Immediately facing the vault that contains all that is mortal of the genial Taylor stood a table with complete telegraphic appliances—the relay, sounder, key and battery attached; the whole encircled by an immense wreath of white artificial flowers, and covered with white crape.

The battery, which stands under the table, was dry, with its wires disconnected, indicating that no vital spark was in it; is of the Daniel form, the most constant and unfailing of galvanic apparatus, and typified the dead operator, who stood first among the foremost of his profession, and who in life never failed to respond to the severest trials of his arduous business. The relay, sounder and key were without springs, and were voiceless and motionless, like the dead. Beside the table stood a messenger boy, but no message of poor Taylor's receiving will ever be given him.

TELEGRAPHERS' MUTUAL BENEFIT ASSOCIATION.

The annual meeting of the Telegraphers' Mutual Life Insurance Association was held, as advertised, at 7½ P. M., Wednesday, Nov. 5th, at 145 Broadway, N. Y. A large representation from abroad was present. The meeting organized promptly by the appointment of Mr. J. D. Reid as chairman. At the invitation of the chairman, after a brief personal introduction, Mr. W. O. Lewis, of New York, and Mr. James F. Morrison, of Baltimore, made brief addresses, felicitating the Association upon the work it had accomplished, and expressing hopes for its future usefulness.

At the close of their remarks, Hon. William Orton, who is a member of the Association, entered the room, and was warmly welcomed. On invitation of the chairman, Mr. Orton spoke about as follows:

MR. CHAIRMAN AND GENTLEMEN: I need not, I trust, assure you how entirely I sympathize with the purposes you seek to accomplish by this meeting. Charity is one of the first and highest duties imposed upon us by God and by virtue of our own humanity. It ceases to become burdensome in proportion as it becomes universal.

That men engaged in a common occupation, united together by the ties which spring from daily association, should conceive for each other a warm attachment, is but natural. That men so engaged and so related to each other should feel inclined to stand together and contribute to each other's necessities, and especially seek to make provision for the helpless, the aged, and the young that are left behind us when we are taken away, is also but an instinct of humanity. When, therefore, the suggestion was first made to me some years ago, of the formation of a Universal Life Insurance Association for the profession, I gave it my hearty personal encouragement; at the same time it did not seem proper that, officially, I should seek to exert my influence in bringing it about.

I do not now remember how long ago it was that after submitting the matter of your organization to the attention of the Executive Committee of the Western Union Telegraph Company, and anxious that they should sympathize with it, I was authorized by them to make a proposition that if the membership should be so increased as to enable a payment of $1,000 n the event of the death of a member of the Association, and limit payment to that amount, that the Company would contribute $100 in addition thereto. My recollection is, that prior to that time, the amount the Association was able to pay was only $400 or $500. Subsequently, under the active exertions of the gentlemen who took an interest in it, the membership was so far increased as to enable the Association to make an appropriation of a $1,000 in every case of the death of a member. $1,000 seemed to me as much as an association of this kind was called upon to pay. To be able to do that was a sufficient success. In order to contribute to this result, I induced the action on the part of the Executive Committee. I had lost sight of the matter until, on inquiry, I was surprised and gratified to find that the membership had become so large that the condition the Executive Committee had attached to the contribution of $100 had become inoperative. Yet, while rejoicing at this prosperity, I apprehended a condition of things might ensue which would prove burdensome, and lead to such a decline in membership that the payment of $1,000 could not be continued.

Now, I do not know whether there is any danger of such a result, and am not prepared, at this moment, in view of the fact that the term of the offer of the Executive Committee has expired, to make a renewal of that offer. I have no authority to do so. But I will say, that such influence as I may possess will be promptly rendered to bring about this result, and bring the Company in direct relations with the Association, if deemed by you advisable.

I trust I shall be acquitted of any intention to make a matter of business out of this. No one realizes more fully than I do how much the prosperity of the Company, over which I have the honor to preside, depends upon the loyalty and fidelity of its employees. No management would be entitled to the respect, loyalty and fidelity of such a body of men as, I am proud to say, compose the force of the Western Union Company, if it did not take some fitting opportunity to testify, not merely their respect for them individually, but their sympathy with them in the common affairs of life. So far as I can do so, I wish now to earnestly represent and express to you how much the Company appreciate the integrity and fidelity of its men, and how much we attribute to them that great measure of success that has attended the progress of our business for the last few years. I have not come here officially to make any suggestions but, in my capacity as a member of the Association, to contribute, so far as I am able, by way of suggestion and advice, as I may be invited so to do, towards making the Association a success. Yet, if I can do anything in my official capacity—anything on the part of the Company—towards that end, I pledge to you to continue my earnest efforts and good offices in that behalf.

REPORT OF THE TREASURER.

The following is the report of Mr. A. S. Brown, the Treasurer, which, on being read, was accepted and ordered to be filed:

NEW YORK, Nov. 5, 1873.

Balance on hand Nov. 1, 1872		$2,905 72
Received from 475 new members, 1677 to 2151		712 50
Assessments		18,545 31
Interest to June 30, 1872		207 27
		$22,370 80
Printing Manual	60 00	
Books and stationery	27 65	
Clerical assistance	150 00	
Miscellaneous	6 35	
Postage and printing	331 56	
Current expenses	$575 56	
Paid heirs of:		
Andrew Ainsworth	970 60	
Charles H. Baker	970 33	
E. A. Hanvey	982 33	
J. T. Elliot	974 33	
R. S. Raymond	989 50

Advance payments on future assessments	90	
		6,731 00
Credited to reserve fund		1,725 15
		$8,456 15

A. S. BROWN, *Treasurer.*

SECRETARY'S REPORT.

Your Secretary respectfully submits the following report for the year ending Nov. 5th, 1873:

Number of deaths	19
Number of new members received	475
Number of certificates canceled on account of deaths, failures to pay assessments, and resignations	251
Number of members in good standing at the beginning of the year	978
Number actually in good standing at date	1,230

Since the organization of our Association there have been a total of 2,151 certificates issued, 921 of which have been canceled.

Early in the year a system of agencies, or as they might, perhaps, be more properly styled, Assistant Secretaries, was inaugurated, followed by the most satisfactory results. Those selected to act were, in most cases, old members who had previously taken much personal interest in the affairs of the Association, and who were the choice of the members in their respective localities. I wish, in this connection, to acknowledge the promptness with which these gentlemen responded to an invitation to act, and for the zeal and fidelity with which the duties pertaining to their office have been discharged.

The agents have been the principal means of not only securing to us large accessions to our membership, but, through their care in approving applications, a better class (as regards physical condition) of new members has been received. This is proved by the fact that the name of only one applicant accepted during the year now appears on the mortuary list. Great care has been taken in accepting new members. In cases where the applicant was not well known to an officer or agent of the Association, or any doubt existed as to his physical condition, a certificate of health from a reputable physician was insisted upon.

Through the efforts of the agents the delinquent list has been kept at its minimum, and notwithstanding the unusual number of deaths during the year, remittances have, in general, been prompt and satisfactory. The loss of valuable letters in the mail, a source of much ill-feeling and vexation up to the beginning of the present year, has almost ceased to be complained of.

The Post-office department has served us well, and I know of no instance, during the year, in which there is reason to think it has been at fault, This is somewhat surprising, when it is considered that we have sent and received upwards of 25,000 letters and circulars through the department. What little trouble has been experienced, I am satisfied is owing to the carelessness of the writers themselves in improperly addressing or stamping their correspondence.

In consequence of the numerous complaints from members whose means were limited, and who could not afford to pay the heavy tax imposed by so many deaths as we have had during the year, it was deemed wise, early in the Summer, to devise some measure to relieve this numerous class.

Two schemes were proposed to accomplish this object; one was to divide the membership into classes of 500 each, designate each class as A, B, and C, and to give a member the option of belonging to one class or all. The other plan, first suggested by the Hon. Wm. Orton, was to limit payments in case of each death to $1,000, the excess paid in on any assessment to be credited to the reserve fund, which, in due time, would be drawn upon to pay a death claim, instead of assessing the members for the same. The first plan was open to the objection that it would involve too much clerical labor, and be too complicated. The second was simple, would cause no additional work in keeping the books, and it was thought that $1,000 was as great a sum as such an institution as ours should undertake to pay at any one time. An expression of opinion of the members in general, on the expediency

of adopting this latter plan, was solicited. Much to the surprise of the officers, it met with considerable opposition, which could only be accounted for on the ground that the proposition was not thoroughly understood, and while, doubtless, a clear majority were in its favor, it was thought best, in deference to the opinions of the minority, to postpone the whole subject until this annual meeting. The association has grown so large, and the labor connected with keeping the books, and corresponding with members, has increased so greatly within the past two years, that some provision should be made for remunerating, in a suitable manner, those upon whom the work shall hereafter fall. The present officers cannot, under any circumstances, serve another year, on account of other duties, and it becomes a serious question to determine what arrangements shall be made for the future.

In view of these important considerations, we are glad to see so many present from points outside of New York, to share in our deliberations for the ensuing year.

D. R. DOWNER, *Secretary*.

On motion, the report of the Secretary was accepted, and placed on file.

Mr. A. S. Brown, from the committee appointed to secure a charter from the Legislature, reported that, on consultation with gentlemen of experience, it was decided to report against any such application, as likely to involve the Association in difficulties which would not be offset by any equivalent advantages.

On motion, the report of the Committee was accepted, and the committee discharged.

Mr. A. S. Brown submitted a new form of Constitution and By-laws, which were discussed *seriatim*, and adopted, as follows:

CONSTITUTION AND BY-LAWS OF THE TELEGRAPHERS' MUTUAL BENEFIT ASSOCIATION.

ART. I.

This Association shall be known as the Telegraphers' Mutual Benefit Association; its object being to aid and benefit the families of deceased members.

ART. II.

Its officers shall consist of a Treasurer and Secretary.

ART. III.

There shall be an Executive Committee of five, composed of the Treasurer, Secretary and three other members of the Association.

BY-LAWS.

RELATING TO MEMBERSHIP.

I.

Any person who is, or who has been, employed in telegraph service, in any capacity, may become a member of this Association upon payment of the required fees, providing such person is acceptable to the Executive Committee.

II.

Any member who has become delinquent through failure to pay assessments, may be restored by a unanimous vote of the Executive Committee, upon filing with the Secretary the proper form of application, and paying back dues, and an additional sum of one dollar and a half.

III.

FEES AND BENEFITS.

The initiation fee shall be one dollar and fifty cents, and in addition thereto a further sum, to be determined in the following manner, to wit: the amount in the reserve fund of the Association shall be divided by the whole number of members at the time of the application, and the quotient less any remaining fraction of a dollar, shall be added to the initiation fee as above.

IV.

Immediately after receiving notice of the death of a member, the Treasurer shall (except as hereinafter provided) assess each remaining member one dollar, payable within thirty days of the issue of the assessment call, neglecting to pay which during the time specified, the delinquent shall forfeit all claims to the benefits of the Association, and shall forfeit membership at the expiration of 60 days, and be restorable only as provided in Section II. of the By-Laws. Upon the death of a member the Treasurer shall, on application from the heirs, pay over to them a sum not exceeding one thousand dollars. If the amount received from the members under the preceding arrangement is not sufficient to meet this demand, the deficiency shall be made good from the reserve fund of the Association, if said fund is sufficient for the purpose, it being the intention to pay to the heirs of all members the exact sum of one thousand dollars.

VI.

Whenever the reserve fund shall be sufficient in amount to pay one or more assessments without reducing the reserve below three thousand dollars, such assessment shall be passed, and the claim of the heirs in such case shall be paid by the Treasurer from this fund. Provided, that when the membership exceeds 2,000, the minimum shall be increased to $6,000, and the Executive Committee may at any time, by a vote of not less than four of its members, order a claim paid from the reserve fund without assessment when the fund is sufficient for the purpose.

VII.

DUTIES OF OFFICERS.

It shall be the duty of the Treasurer to preside at all meetings of the Association, receive all moneys from the Secretary, pay properly audited bills and claims, sign all certificates of membership, and prepare and present a report to the annual meeting.

VIII.

The Secretary shall keep the records of the Association, sign all certificates of membership, maintain such correspondence, and issue such notices as may be necessary. He shall receive all moneys from members, and pay the same to the Treasurer, and present a report at the annual meeting of the Association.

IX.

The Executive Committee shall have general supervision over the affairs of the Association, and decide all questions which may arise.

The Committee will meet at any time at the call of the Treasurer.

X.

MEETINGS, &c.

A meeting for the election of officers and members of the Executive Committee, and the transaction of such other business as shall come before it, shall be held annually on the second Wednesday in November of each year. The officers elected shall serve for one year, or until their successors are elected. In case of the death of a member of the Executive Committee, the remaining members shall have the power to fill the vacancy until the time of the next annual election.

XI.

Special meetings of the Association shall be called upon the written request of twenty-five members.

XII.

The Secretary may appoint, subject to the approval of the Executive Committee, a number of members to act and be known as agents, whose duty it shall be to exercise a general supervision over Association matters in their respective districts.

They shall receive and forward to the Secretary applications for initiation or restoration, with their endorsement of approval, or otherwise, as the case may be, keeping on hand the necessary blank forms, receive payments from members, giving receipts therefor when desired, and remitting to the Secretary all money on hand at the expiration of 30 days from the date of an assessment, advise the Secretary of changes in address of members, and in the event of the death of a member, attend to payment to the heirs, under the direction of the Treasurer and Secretary.

XIII.

The books of the Association shall always be open to the inspection of any member thereof.

XIV.

The Secretary shall receive compensation for the performance of his duties at the rate of five hundred dollars per annum.

XV.

All expenses of this Association, including the pay of its officers, shall be paid from the reserve fund of this Association.

XVI.

The *status* of all persons connected with the Telegraphers' Mutual Life Insurance Association is maintained under this Constitution and By-Laws.

ELECTION OF OFFICERS.

Mr. Wm. Holmes, of the Tariff Bureau, was unanimously elected Secretary of the Association for the ensuing year, and J. D. Reid, Treasurer. A vote of thanks to the former officers for their faithfulness and zeal for the past year was passed, and the meeting adjourned at a late hour.

The "foreign" delegates were:

F. A. Armstrong, Cincinnati, O.; H. A. Clute, Harrisburg, Pa.; James Merrihew, Philadelphia, Pa.; Frank Morrison, Baltimore, Md.; M. Marean, Washington, D. C; G. B. Hubbell, Hartford, Conn.; W. J. Denver, Springfield, Mass.; E. A. Beardslee, Boston, Mass.; Geo. A. King, Albany, N. Y.; D. L. Pike, Syracuse, N. Y.; J. W. Tillinghast, Buffalo, N. Y.; R. O'Brien, Scranton, Pa.; A. J. Reinhold, Mott Haven, N. Y.; John Fuller, Easton, Pa.; C. W. Schermerhorn, Plainfield, N. J.; C. W. Gulick, Plainfield, N. J.; D. C. Hinsdale, Indianopolis.

On motion it was

Resolved, That all who have been members of the Telegraphers' Mutual Life Insurance Association, and are delinquent through non-payment of dues to an amount exceeding $10, may, with the approval of the Executive Committee, renew their membership in this Association on the payment of that sum; this resolution to remain in force till Jan. 1st, 1874.

It may be as well to add that the operation of By-Law 3 is to make the initiation fee of applicants in the present state of the reserved fund, one dollar more than the ordinary admission. This is entirely fair, the present membership having, by their payments, accumulated the present reserved fund. *Remit money only to William Holmes, Sec.*

GEORGE DAFT, telegraph operator, was instantly killed on Sunday morning last at Fulton station, on the Baltimore and Potomac Railroad, by jumping from a train while in motion. He bore an excellent character.

We neglected to note, in our last, the death of C. A. McDaniel, acting Manager at Colvert, Texas, and his wife, Oct. 13th; and of Taylor Adams, operator at New Orleans, on the 16th ult.—all of yellow fever.

DEATH OF TELEGRAPHIC MANAGER T. R. TERRY.

COLUMBUS, GA., Oct. 21st.

Mr. Thomas R. Terry, manager of the Southern and Atlantic Telegraph Company at Montgomery, died of yellow fever this morning at 2:30 o'clock, at the residence of his father-in-law, at Mitchell Station, on the M. and E. R. R. He was a native of Virginia, and about thirty years of age. He leaves a lovely wife and a sweet little girl to mourn their irreparable loss. Not a nobler man could be found in any walk of life. He was a reliable man, esteemed by everybody that knew him. He leaves numerous friends to mourn his untimely death.

THE DEATH OF CORNELIUS McCARTHY.

At a meeting of the employés of the Western Union Telegraph Company to commemorate the memory of our departed and esteemed associate, Cornelius McCarthy, the following preamble and resolutions were adopted, viz:

"*Whereas*, we are called together to mourn the loss of our esteemed associate, Cornelius McCarthy, by death; therefore,

Resolved, That we deeply mourn the loss of our associate, combining as he did the elements of a true man while living, and who leaves for us a practical and noble example.

Resolved, That to his family and relatives we tender our heartfelt sympathy and condolence.

Resolved, That we wear the usual badge of mourning for thirty days, and that a copy of these proceedings be furnished his family and relatives, and that the same be published in the Memphis city papers and the telegraph journals.

TELEGRAPH COMPANIES.

THEIR RIGHTS IN CITIES—OPINION OF THE COUNSEL TO THE CORPORATION.

Telegraph companies incorporated under the laws of the State of New York are legally authorized to extend their wires in the usual manner through the streets of the City of New York.

The right of the Common Council of that City to regulate the erection of telegraph poles, and the duty of the Commissioner of Public Works to remove obstructions, do not empower those authorities to substantially abridge or materially interfere with the right of such companies to construct their lines in any street or avenue.

LAW DEPARTMENT,
OFFICE OF THE COUNSEL TO THE CORPORATION,
NEW YORK, Oct. 25, 1873.

Hon. George M. Van Nort, Commissioner of Public Works:

SIR: A communication from your department requests my opinion upon the legal right claimed by telegraph companies to extend their lines through the streets of the City of New York.

The place and progress of the telegraph in modern civilization have been so recent and rapid that those few persons who do not directly participate in its benefits may be pardoned for overlooking its usefulness and necessity, when, like all public improvements, it causes inconveniences to localities and to individuals. In populous communities its obstructions are, of course, the most felt; while it is precisely there that its works are the most needed. It is frequently objected that the prevailing system of carrying the wires upon poles should give way to some plan of subterranean communication. No such change has been found anywhere practicable, at least to any general extent; and in our American cities, which are all, even including New York, in a conspicuously unfinished state, it is difficult to see how wires could be so laid in the earth as not to be daily interfered with by excavations required in the erection and alteration of buildings. Interruptions to the continuity of the lines would also result, though to a less extent, if carried, as some propose, over the tops of buildings. It is known, however, that large sums have been expended by leading companies in obtaining plans for some system less objectionable than the present, in point both of convenience and sightliness. It would require the expenditure of millions of dollars to effect any general change. Both public opinion and the interests of the companies themselves will undoubtedly require the outlay of the money when practicable plans shall have been discovered and invented; but even when that time shall have arrived, it cannot be expected that reconstructions of such magnitude and changes so extensive can be the work of a day.

The Constitution of the United States clothes Congress with the express power of regulating commerce with foreign nations, and among the several States. (Article 1, section 8, subdivision 4.)

In 1866 Congress passed a statute, entitled "An Act to aid in the construction of telegraph lines, and to secure to the Government the use of the same for postal, military, and other purposes." That Act gave to any telegraph company then organized or thereafter to be organized under the laws of any State in the Union, the right to construct, maintain, and operate lines of telegraph through and over any portion of the public domain, over and along any of the military or post roads which had been or might thereafter be declared such by Act of Congress, and over, under, or across the navigable streams or waters of the United States; provided only that navigation should not be obstructed nor ordinary travel be interfered with. Materials for such construction may, under that Act, be taken from the public lands. Dispatches for the Government are to have priority of transmission. The United States may purchase the telegraph lines. (United States Statutes at Large, volume 14, chapter 230, page 221.)

As early as the year 1848 the Legislature of this State enacted a statute for the incorporation and regulation of telegraph companies. By section 5 any telegraphic association is authorized to construct lines of telegraph along and upon any of the public roads and highways, by the erection of the necessary fixtures, including posts for sustaining the wires; provided such construction does not incommode the public use of such roads or highways. By section 6, if any person upon whose lands such posts should be placed, consider himself aggrieved or damaged, he may apply to a County Court to appoint five disinterested persons as commissioners to make a just and equitable appraisal of the damage, and the amount thereof shall be paid by the company. Section 7 enacts that any person who shall intentionally injure, molest, or destroy any telegraphic line or post shall be guilty of a misdemeanor, and be punished by a fine not exceeding $500, or imprisonment in the county jail not exceeding one year, or both, at the discretion of the Court. The provisions of law, of which the substance is given above, will be found in chapter 265, of the laws of 1848, page 392.

In 1853 that Act was amended. By section 2 of the amendatory Act any telegraphic association is authorized to erect and construct from time to time the necessary fixtures for lines of telegraph upon, over, and under any of the public roads, streets, and highways, and also to erect and construct such fixtures upon, through, and over any private lands, subject in the last instance to the right of the owner to full compensation to be agreed upon, or, in the event of a failure to agree, a Court to appoint a disinterested commission to appraise and fix a sum in gross as the compensation which the proprietor is to receive from the company. This amendatory Act forms chapter 471 of the laws of 1853, page 931. It must be observed that these Acts contain no condition clothing local authorities with any power, direction, or supervision in the matter. Nor is there any restriction in the application of the two statutes to all parts of the State. It is clear, therefore, that the answer to your first inquiry must affirm the right of telegraph companies, incorporated under the laws of this State, to erect poles in the City and County of New York.

Your second question is, whether these companies must first obtain the consent of the Common Council before they can legally erect poles in this City? My answer must be in the negative. The right conferred upon them is absolute and unconditional. The statutes upon this subject proceed upon the broad ground that the telegraph is an institution necessary to the public good and the convenience of the people at large. To permit the Common Council of a city to prohibit the construction of the fixtures necessary to traverse its streets with a telegraph, would be to clothe a local authority with power to obstruct a great and general public necessity by its own mere will for reasons of mistaken local advantage, or even from mere caprice.

It is true that among the powers granted to the Common Council of New York, by what is known as the Charter of 1873, is the right to regulate the use of the streets and sidewalks for signs and sign-posts, awnings and awning-posts, horse-troughs, telegraph-posts, and other purposes. (Subdivision 9, of section 17, chapter 335, of the laws of 1873.)

This general provision of law contains no implication that a telegraph corporation of this State must obtain the consent of the Common Council to exercise the right legally conferred of erecting poles in the City; nor can the Common Council lawfully act upon the supposition that the power of regulation can be so used as in any way to obstruct or abridge the comprehensive right to place telegraph poles through the public streets. The power of regulation is a power to direct that the erection of the poles shall be done in an orderly manner, with no unreasonable interference with the ordinary uses of the streets, and with no gross and exceptional disfigurement. But as the law itself does not restrict the companies to the use of any particular street, but permits them to carry their fixtures through any of the streets of the City without exception, the Common Council, under the right of regulation, cannot deprive the companies of the full measure of power which the Legislature, for public reasons, has seen fit to confer upon them. Their permission come from the law-making power of the State, and it need not be sustained, nor can it be limited by the action of local authorities.

Your third inquiry is, Can the Commissioner of Public Works authorize the erection of telegraph poles in the City of New York? As such erection is already permitted by law, the right to exercise it is not left to the discretion of either the Executive or Legislative departments of our local government. The powers of the Department of Public Works are broad, and they expressly include the keeping of the streets clear of obstructions. This reasonably implies such power of regulating the use of the streets by a telegraph company, as we have already considered, as also in general terms conferred upon the Common Council; but it does not impose upon the companies the necessity of obtaining from any department of the City Government a permission to use the streets in accordance with the powers conferred by the Legislature. When, however, a telegraph company is about to erect its poles in a street or avenue, the Commissioner may properly issue a permit as evidence in the hands of the company's superintendent that the necessary obstructions are lawful, and your department should so far regulate and oversee the work as to secure public and private interests against unnecessary interference.

As a general rule, there ought in reason to be no conflict between the local authorities of cities and the directors of great public works and improvements. The growth and prosperity of towns, the profitable use of their capital and the interests of their population, including regular employment to labor, must always be promoted by the utmost facilities of traffic, transit and communication. This obvious truth is always acted upon by young communities, but is often fergotten when cities have long grown and prospered. Under proper safeguards, railroads cannot come too near nor penetrate too far. To maintain its commercial pre-eminence, New York must encourage and foster these public enterprises which bring it near to the remotest quarters of the country and the world. In the words of Sir Walter Raleigh, "all those things that cause the greatness of a city are also fit to conserve the same."

I am, sir, very respectfully yours,

E. DELAFIELD SMITH,
Counsel to the Corporation.

THE telegraphic receipts on European and Asiatic business are reported as largely increased in comparison with last year.

NOTES AND QUERIES.

COLDWATER, Mich.—A message originating at a point where there are both W. U. and A. & P. offices, is destined to a point where there is no A. & P. office; is started by A. & P., comes part way, and is handed to our company, to be sent through. Message requires an answer. Party answering does not want to guarantee the collection of tolls. Should it be received, and if received, should it be sent *via* the same route by which it came, or direct *via* W. U. line? If by W. U., and the office at the end of route is unable to find the party, and hence unable to collect toll, is the manager held responsible for the amount of check?

Ans.—Answer under such circumstances should not be accepted unless guaranteed, and should be transmitted wholly by Western Union line.

EASTHAMPTON, Mass.—Please explain, through the columns of the JOURNAL, how many words in the following signature, "Williston Mills, E. H. Sawyer, Treasurer." I claim, according to Rule 9, "Whenever more than one signature is attached to a message, count all except the last, as a part of the body of the message," and the word Treasurer after the signatures, that there are three words in it. By explaining you will greatly oblige.

Ans.—You are correct.

ENQUIRER.—In case an operator at a repeating station is requested to take and repeat a message, as (D. H., no account), should he comply with the request, or should he insist that it must be checked with number of words and reason why D. H., as per rule?

Ans.—When a message has been accepted in good faith and started on its way, a repeating office is required to receive and transmit it, as if in all respects regular. We refer Enquirer to Rule 20, second clause.

J. E. BROWN, Manager, Braceville, Ohio.—Ravenna, Ohio, is 17 miles from here. Tariff Circular taking effect July 1st, 1873, makes tariff 25 cents for less than 25 miles, yet Ravenna, O., is in square 159, and that is 40 cents. There are several other offices in the same fix. Please state whether I am to use distance rate or square rate in such cases?

Ans.—Use "distance" or local rates to all points within 50 miles of your office. The 40c. rate to square 159 is given for the reason that there may be two—perhaps more—offices in that square more than 50 miles apart.

HAMBURG, Iowa.—I find in JOURNALS December 2nd, 1872, and September 15th, 1873, a flat contradiction in regard to counting St. James. Now, is not any name with St. prefixed a surname, and always to be counted as one word, no matter what they may be prefixed to, whether hotels, steamboats, stations, or anything else? Please decide for us and oblige.

Ans.—We believe the answer given December 2, 1872, to be the correct one. If St. James is a surname (and it is well known to be so), then it is one word, and only one, wherever it is used. It is, therefore, as much one in naming a hotel as in the name of a person.

BLACK HAWK, Col.—Quite frequently I hear red messages passing to points out here, and originating (almost invariably) at large offices in the "States." Would it not prevent some errors, and Managers from losing on them, to define through the JOURNAL (again) the limits of half-rate territory?

Ans.—The rate in reference to red messages is as follows: "Half-rate messages may be taken for and received from offices in United States in squares from 6 to 511 inclusive, and 587." No red messages can be taken for places beyond Kansas and Nebraska.

A communication from Warsaw is too blindly and carelessly written for our comprehension.

WE acknowledge receipt of a communication, three folios in length, ending in a "birth" notice, and perpetrated on Form 271, St. Louis, Kansas City and Northern Railway, signed "Opperators." It proves the existence of a candidate for the insane asylum in that district. The advent of the baby may account for it, and we forgive it for that reason only.

JOHN J. FLANAGAN, of the *Utica Observer*, President of the St. John's Temperance Society, and widely and well known in telegraphic circles, has been presented with an elegant gold watch and chain by the members of the society. It was a very deserved honor to a most worthy man.

We acknowledge corrected lists of offices from the following, thanking all for their promptitude:

Pacific Division.
Central Division, 4th, 6th and 7th.
Eastern Division, 2d, 3d, 5th, 7th and 9th.
Southern Division, 4th.

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, NOVEMBER 15, 1873.

SHREVEPORT.

The correspondence growing out of the recent deaths from yellow fever at Shreveport, La., has been placed in our hands. We have read it in tears. There are passages in these letters bursting with the bitterness of sorrow. There are also the evidences of a heroism of which the Company may well be proud, and which has been deeply and fully appreciated. The correspondence is scarcely suitable for publication, yet we make exception in the case of the admirable letter of Superintendent L. C. Baker, which will be found elsewhere. Let no one fail to read it. There is a tenderness throughout which is an honor to him. In fact, this permeates the whole correspondence. The executive letters are touchingly parental and tender. They are fresh evidences of what we have always gloried in, an authority not only approachable but sympathetic. Dr. Green's closing words, in his letter of official condolence with the mother of the noble Jackson, is but a specimen of it all. "Your letter to Supt. Baker has touched the hearts of all in our Executive Management, and you have our tenderest sympathy in your sad affliction. We had been thoroughly advised of the noble character of your lamented son, and his bright promise of honor and usefulness to his family, his friends and the world. May God help you to bear your cross with Christian submission, and provide you friends and comfort to your 'heart filled with sorrow,' and bright cheer to your sad 'home,' now made 'desolate.'" A committee has been appointed to assist the bereaved families.

We add a word of our old friend Saville. Says Mr. Bernard, now manager at Shreveport: "I must tell you of poor, self-sacrificing Alfred Saville. During the time he was with us not a word of impatience escaped him. Forbearing and kind to all who came to him for assistance, he won all hearts. When stricken down, he was a quiet, patient sufferer. Just before death he received a message from his wife, from Grenada, Miss. After it was read to him he said, 'I want for nothing now. I am near Heaven.' All was done to save him, but it could not be. He sleeps his last sleep. No better epitaph could be written for him than our Saviour's words, 'Greater love hath no man than this, that he lay down his life for his friends.'"

We must add the heart-broken language of the mother of Thomas M. Jackson: "My darling boy has sacrificed his life to his sense of duty. The world may applaud, but my heart is filled with sorrow. My home is desolate. My dear child, who loved us so dearly, and was so dearly beloved by us, is gone. Our brightest hopes lie buried in the grave." This noble lad was only seventeen years of age. His father had fallen in battle. He was the hope and support of his mother's home.

We trust that some day a fitting monument may mark the place where rest these heroic men. Meantime, we may use the language of Byron to Kirk White:

> "No marble marks thy couch of lowly sleep,
> But living statues there are seen to weep.
> Affliction's semblance bends not o'er thy tomb;
> Affliction's self deplores thy youthful doom."

In an address recently made in England, the speaker, alluding to the intimacy yearly increasing between the telegraph and other industries and inventions, claimed, very properly, that the range of enquiry by telegraphic workers must also be widened. Nothing could be more sensible. The great highway of the world's thoughts and activities touches all the cross roads of human interest. It may truly say, "whatever concerns man concerns me." It is already harnessed to every storm. It outlines every railroad. It feeds and animates the press. It is the right hand of peace and the necessity of war. It touches all things.

The Postmaster-General will of course introduce into his annual report the subject of the postal telegraph. We would not stop him in doing this if we could. It is well that Congress should discuss every measure where public benefit seems likely to be affected. No company can long defeat the provision of what is intelligently found to be a public necessity. Of course we deny that the tele graph in Government hands can be anything but a public evil. But we do not discuss that now. We wish, however, to say a word on a subject connected with it which some may appreciate.

We have claimed, in another article, that the confidential nature of the business tends to create a sentiment of honor among telegraph men. We emphasize that statement and make another. We believe that the contact of the public with the receivers and managers of offices, and the necessity of courtesy in the transaction of business with them on the part of these receivers, establishes a relationship of mutual helpfulness which must to a large extent disappear as soon as these men become, if they ever do become, governmental employees. Even the same men will meet the public on a totally different basis. Now a man feels that he retains office somewhat on the public estimate of his fitness and desire to oblige. The public can readily reach his employer. He is in a manner in the employ of the public. As a Government official he will become the simple wheel of a machine, grinding out his daily duty, and, independent of the public good-will, will cease to exert himself to merit it. Such, we believe, to be the drift of official service. It is the drift of human nature. Where responsibility ceases, indifference begins. The public cannot afford the change.

The annual meeting of the Telegraphers' Mutual Benefit Association, held Nov. 5th, was a very spirited affair, and was largely attended. Among the "foreign" delegates were F. A. Armstrong, of Cincinnati; D. C. Hinsdale, of Indianapolis; Jas. Merrihew, of Philadelphia; M. Marien, of Washington; R. O'Brien, of Scranton, Pa.; D. L. Pike, of Syracuse, N. Y.; E. C. King, of Albany, N. Y.; E. A. Beardslee, of Boston; C. H. Schermerhorn and —— Gulick, of Plainfield, N. J.; Supt. H. A. Clute, of Harrisburg; W. J. Denver, of Springfield, Mass.; A. J. Reinhold, of Motthaven; John Fuller, of Easton, Pa.; G. B. Hubbell, of Hartford, Conn.; J. W. Tillinghast, of Buffalo; James F. Morrison, of Baltimore. It was the first thoroughly represented and enthusiastic meeting of the organization. President Orton was present during the evening, taking a free and cheerful part in the discussions, and was heartily welcomed. It was observable that his presence in no way interfered with the freedom of discussion, but seemed to give it zest and point. A large amount of business was done, and in a way highly creditable to the intelligence of all concerned. We venture to say that in very few organized bodies could a Constitution and By-Laws, thoroughly remodeled and sharp and specific in their details, have been as fully canvassed, trimmed, and adopted in a single session of three hours. The meeting owed much of its intelligent direction to the foreign delegates, among whom we may be allowed to instance Armstrong, of Cincinnati, and Hinsdale, of Indianapolis; and was kept lively by the sprightliness and bonhommie of Morrison, of Baltimore. We congratulate the Association, also, on the election of Mr. William Holmes, of the Tariff Bureau of the W. U. Telegraph Company to the office of Secretary. No better selection could have been made, although the refusal to accept election by Mr. David R. Downer, who has, during these six years, performed so conspicuous labor for the Association, and to whom it is very largely indebted for its existence and success, gave general regret. We are glad, however, that both Mr. Downer, and Mr. A. S. Brown, to whose clear and practical minds the new order of things is due, and Mr. A. B. Chandler, the accomplished Superintendent of the 5th District, are retained as the Executive Committee.

We bespeak for this worthy organization, called into being as it was by a desire to take from death some of its darkness and provide for the bereaved, a larger and wider welcome and participation. Its membership should be much enlarged. Its history has been one of continued blessing. Its payments during the past year have exceeded $22,000. During the last six years it has entered nearly fifty homes, carrying cheer and hope. We trust its future may be even more successful than its past.

Digitized by Google

THE USE OF POSTAL CARDS.

We beg to call special attention to the fact that a postal card can only be used a second time by affixing a three cent stamp thereon. It ceases to be a postal card after its first use. This is official. If it it a convenience to place the answer on the same card, it should be returned in a three cent envelope or a three cent stamp put on its face. Parties returning postal cards with a one cent stamp thereon, are informed that they expose the receiver to double postage. From information before us, it is done to a large extent in the company's service.

WE call attention to another evil. Managers and operators are aware of the fact that letters and papers are frequently lost for the reason that the name of the office to which they are directed may not be the name of their post office. In order that future difficulty may be prevented, managers are requested to send their post office address, if different from the name of their office, to the Tariff Bureau for publication.

Mr. STEARNS informs us that the Duplex is working successfully between London and Dublin, a distance of about 400 miles, 70 of which is cable and six underground, with no repeaters.

Thanksgiving day is coming. It seems a blessed thing that turkeys cannot read and don't understand English. A turkey is a wondrously grave creature to be the expression of thanksgiving. And yet the gloomy bird seems to be the universally accepted medium of gratitude. This may be why he looks so solemn and gives these lugubrious angry gobblings as he struts with melancholy tread through the barn yard. Who knows but that gobble is the turkish of "alas, to what base uses must we come at last!" for to be gobbled up by universal proclamation must seem exceeding base to a turkey of the period. How Henry Bergh can have the face to hand his plate for a second joint on Nov. 27th, we cannot imagine.

Well, the turkey is supposedly slain and the cranberries picked. We hope all our 10,000 readers may have a well-heaped dish of each. Eat both with grateful hearts. The year has been full of mercies to you. Give the day to looking at the credit side of your last year's journal. Hasn't the sun shone for you more than half the year? Are you not proud of your connection with a pursuit which civilizes and unites and blesses the world? Is it not a good thing to have daily duties which increase one's self respect and quicken the sense of honor? Is it not a source of gratitude that in so vast a business the executive influence is kind and humanly and sympathetic, and that there is no harsh band of authority crushing out genius and stifling honest endeavor. Of this there is no better evidence than the existence of the JOURNAL. The poorest boy that runs his errand with a message may write for it, if he writes intelligently, and have a place. Like a smile it leaves the executive walls and enters wherever a click of magnet o'er all this broad continent says "come in." We trust the day may come cloudless to all. We hope also that while you eat your turkey you will remember those who are chickenless, and mark out for yourselves a year of brighter work and more widened sympathy.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Nov. 6th, 1873.

On December 1st, Money Order offices will be established at the following named points:

In G. T. Williams' District:

Washington C. H., Fayette Co., Ohio; Washington, Davies Co., Ind.; Aurora, Ind.; Olney, Ill.

In C. O. Rowe's District:

Greensbury, Pa.

Plainfield, N. J., in D. H. Bates' district, has been closed as a money order office.

G. H. MUMFORD,
Vice-President.

SAN DIEGO has been reached by telegraph.

STUDENTS will be interested in reading Partrick, Bunnell & Co.'s advertisement on the following page.

THE *N. Y. Times* is publishing a serial, based upon ancient mythology, entitled "The New Cable."

PHOTOGRAPHS of the new Western Union building, New York, 25 cents. Address John Brant, 145 Broadway, N. Y.

Two deaths of members of the Telegraphers' Benefit Insurance are announced:

At St. Louis, C. W. Hills, formerly of Baltimore, Oct. 10, of pneumonia.

At Memphis, C. McCarthy, Nov. 8, of yellow fever.

THE telegraph ship Africa left Woolwich with 850 miles of cable to be laid between Alexandria and Brindisi. On completing this work the Africa will lay a cable across the Straits of Messina.

WE see it stated that the Paris evening journals get their news of the Bazaine court martial at Versailles by carrier pigeons, the Government regulation of the telegraph rendering it too slow for their use. Will Mr. Cresswell put that in his official pipe and smoke it?

WE regret to notice among recent reports several discharges for drunkenness and as many for default. And yet these cases are marvellously few considering the extent of the service, and the temptation to intemperance incident to a sedentary occupation.

THE Presidential mansion and the Government departments are being connected telegraphically with each other and the Capitol. The number of wires connected with the Capitol have been largely increased, and business will be greatly facilitated thereby.

THE question of the day seems to be, "Can intermediate earths be used to facilitate a through current during a storm?" We are waiting for a statement of the theory which a western official says he "established on the spot" where a ground wire was thus employed.

We learn by recent advices from London that Mr. Stearne's duplex machinery is still working its way more and more successfully into European telegraphy. The General Superintendent of Telegraphs in Russia has announced that it is now in successful operation between St. Petersburg and Moscow, a distance of 400 miles. Such a fact gives us a better idea of Russian civilization. And it is not without interest that we reflect that to a quiet and unpretentious American the great powers of Europe are indebted for the most valuable of modern inventions,

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 BROADWAY, NEW YORK,
November 15, 1873.

To all Offices on W. U. Lines:

The following changes and additions have been made since the date of the last Circular:

GENERAL INFORMATION.

Winsted and West Winsted, Conn., are one and the same place. The P. O. A. is West Winsted.

Madison, Ark., closed.

Claymont, Del., closed.

Half-rate messages can now be taken for Pensacola, Fla.

Carr and Bluff Hall, Ill., re-opened.

Allens, Ind., re-opened.

Lisbon, Me., re-opened.

Neponset, Mass., closed. Messages for Neponset will hereafter be delivered from Boston, Mass. Charges for delivery fifty cents.

Hereafter the "Tariff for Other Lines" to Barnsville, Md., will be 45 and 1 from Washington, D. C., or Point of Rocks, Md.

Mackinaw City, Mich., closed.

Au Gres, Lumber Boom, Mich., closed.

Martinsville, Miss., closed.

Water Valley, Miss., re-opened.

Attention is called, *for the third time*, to the fact that Lincoln, Neb., is a W. U. office, in square 474; business should be sent *via Atchison, Ks.*, and CHECKED DIRECT.

Franklin, Nev., closed.

Stough and Lewis, Nev., closed.

Woodland, Nev., closed.

Business for Rollinsford, N. H., will hereafter be checked to Great Falls, N. H., instead of South Berwick Junc., as heretofore.

Godwinville, N. J., closed.

Genesee, N. Y., changed to Wellsville.

Killawog, N. Y., closed.

So. Granby, N. Y., closed.

Londonderry, N. S., closed.

Medina, O., is now a W. U. office, square 180, check direct.

Glenwood, O., closed.

Glen Rock, Pa., closed.

Middaughs, Pa., closed.

Sinnemahoning, Pa., closed.

Fort's Station, Tenn., closed.

Meadow Creek, W. Va., closed.

NEW OFFICES.

401 Beebe, Ark.
300 Allendale, Ill.
327 Gridley, Ill.
261 Ossian, Ind.
367 Oxford Mills, Iowa.
28 Montague, Mass.; check Greenfield, Mass.
269 Allyton, Mich.
240 Franciscoville, Mich.
* Summit Sta.....25 2 { 200 Detroit, Mich. / 211 Toledo, O.
447 Raymore, Mo.
101 Wellsville, N. Y.
2 Spring Hill, N. S.
191 Black Creek, O.
191 Fredericksburg, O.
146 Port Royal, S. C.; check Beaufort, S. C.
484 Lovelady, Texas.
* New River Falls, W. Va., { 65 4 182 Huntington, W. Va. / 50 3 133 Greenbrier, W. S. Spgs., "

OFFICES HAVING SHEET C.

The following offices should be added to "Sheet C," and business checked direct:

24 Bloom, Wis.
7 Greenleaf, Wis.
2 Horn's Pier, Wis.
9 Lake Shore Junc., Wis.
9 West Bend, Wis.
29 Wilton, Wis.
38 Utica, Minn.

Austin, Minn., and Postville, Iowa, formerly Other Line offices, but checked direct as per Sheet C, are now W. U. offices, and should be checked direct at W. U. square rate.

The notice of the opening of Medina, O., office in JOURNAL of Oct. 15, 1873, should be disregarded.

ATLANTIC CABLE BUSINESS.

We are notified that the Cable between Falmouth and Lisbon is again repaired. Business can now be sent "via Falmouth."

WILLIAM ORTON, *President.*

PARTRICK, BUNNELL & CO.'S

Champion Learners' Instruments.

COMBINED No. 1 SOUNDER AND KEY, with BATTERY, OFFICE WIRE, CHEMICALS, and a thorough BOOK of PRACTICAL INSTRUCTION in the Art of Telegraphy,

Which latter gives all necessary directions for setting up the Battery and complete apparatus, and operating them for practising or communicating purposes.

THIS IS WARRANTED TO BE, BEYOND ALL COMPARISON, THE BEST APPARATUS EVER OFFERED FOR THE USE OF STUDENTS OF TELEGRAPHY.

Being excellent Morse instruments, substantially made and nicely finished, with nothing left out of their construction which pertains to a Complete Sounder and Key Combination Set. Nothing made in miniature, or in awkward and unusual shape, as is done with the very cheap affairs usually offered as Learners' Apparatus. They are equally well suited

For TELEGRAPHIC SCHOOLS OF INSTRUCTION, For PRIVATE TELEGRAPH LINES, and For CITY WIRES OF TELEGRAPH COMPANIES.

The BATTERY which accompanies the Learners' Outfit is a full-sized Callaud, the same as the best cells used by Telegraph Companies for main battery, and gives sufficient power to produce a loud, clear sound from the instrument, the Sounder of which embodies the same remarkable principles of sound which have made our "Giant Sounders" so famous and popular among telegraphers.

The BOOK OF INSTRUCTION is a clear and practical explanation, by an experienced telegrapher, of every fact and principle of modern telegraphy and its apparatus which a student of the art could possibly require to obtain, in undertaking to become an accomplished sound operator.

PRICE OF APPARATUS complete, with Book of Instructions, Battery, Wire, and all necessary materials for one complete office outfit, ready for shipment, $10, sent by Express, C. O. D.; or $9.50, if money order for that amount be sent in advance. The latter plan will additionally save the purchaser the Express charges for returning money.

IN the course of correspondence of an ordinary character, it has become a common and convenient method to give answer on the same sheet or on the face of the letter received. We wish it to be remembered that this cannot be done with postal cards. When used a second time, even if a one cent stamp is added, the charge to the receiver is six cents. The office at Springfield, Ill., has had to pay for several such errors, and requests us to call attention to it.

SECOND-HAND RELAYS.

A large lot of well polished and good working Relays for sale cheap.

Also several sets of

HICKS' REPEATERS,

In perfect order, at a nominal price.

GEO. H. BLISS & CO.,
41 Third Avenue,
Chicago, Ill.

MARRIED.

KEMP—PROCTOR.—At Wilford, Conn., September 4th, by Rev. A. J. Lyman, Lewis D. Kemp, Manager W. U. Telegraph, to Miss Eva Bell Proctor, of Dexter, Me.

MITCHELL—HALSEY.—At the residence of the bride's father, Halseyville, N. Y., October 16th, by the Rev. Lewis Halsey, Mr. J. J. Mitchell, Manager W. U. Telegraph, Ludlowville, N. Y., to Miss Lizzie M. Halsey, of the former place.

SCHUSTER—LOGAN—On Saturday, Oct. 18, at West Galway, Fulton Co., N. Y., by the Rev. David Anderson, Charles A. Schuster, of the Tariff Bureau of the Western Union Telegraph Co., New York, to Jennie D. Logan, both of New York city.

BORN.

HOAG.—In Oakland, Cal., Oct. 25, to Charles P. Hoag, of the W. U. Telegraph office, San Francisco, a daughter.

WILSON.—On October 27th, 1873, a son to Arch. Wilson, Jr., manager W. U. Telegraph Co., Balto City.

TELEGRAPH OFFICE

OF

Anders' Magneto Printing Telegraph Instruments.

Telegraph Office of the BOSTON AND ALBANY RAILROAD,
BOSTON, Nov. 3, 1873.

MR. GEO. L. ANDERS.

Sir: Your "Magneto Printing" Telegraph Instruments, which have been in use on our line for the last eight months, have proved to be *very reliable*, and we would recommend them to any parties who want Printing Instruments.

Signed,
Z. GIBBS,
A. F. TUCKER, } Operators.

Office of the BOYNTON PACKING COMPANY,
BOSTON, Nov. 4, 1873.

MR. GEO. L. ANDERS.

Dear Sir: Your Magneto Printers, which have been on our line four months, have worked *splendidly*, and given entire satisfaction, and we do not hesitate to recommend all who may have use for telegraph instruments for *private lines* to purchase your Printers in preference to any others we have ever seen.

Yours truly,
H. P. SANBORN,
I. CHEEVER FULLER.

For RELIABILITY, RAPIDITY and ECONOMY combined,

ANDERS'

MAGNETO PRINTING TELEGRAPH INSTRUMENTS

are superior to any others yet produced. They have straight Key-boards, and will print *as fast* as any person can select the letters on the keys. Messrs. Sanborn & Fuller say they often send thirty words per minute by these instruments on the line of the Boynton Packing Company.

NO ACID BATTERY

is used. The currents being generated by induction from permanent magnets, the instruments are always ready for use, and all expense and trouble of Acid Batteries are avoided.

RELIABILITY.

They are so simple in construction that it is almost impossible (with ordinary care) to get them out of order, as has been proved by thorough trials.

We also continue to manufacture

ANDERS' MAGNETO DIAL TELEGRAPH INSTRUMENTS,

which are in use on the Police Lines of Boston, also on numerous private lines.

These instruments will work on longer lines, and with larger Dials and Indicators than any other Magneto Dial Instruments made.

Manufactured and for sale by

E. B. WELCH and GEO. L. ANDERS,

30 HANOVER STREET,
BOSTON, MASS.

RED STAR LINE.

ANTWERP SERVICE.

APPOINTED TO CARRY THE BELGIAN AND UNITED STATES MAILS.

		From Antwerp.	From Philad'a.
"VADERLAND," Captain Vander Heyden,	2800 tons.	Nov. 12.	Oct. 22.
"RYDAL HALL," Captain Collin,	2114 tons.	Oct. 11.	Nov. 5.
"NEDERLAND," Captain H. W. James,	3000 tons.	Oct. 25.	Nov. 22.
"SWITZERLAND," Captain ——,	3000 tons.	Building.	

PRICES OF PASSAGE:

Cabin.....$100 gold.
Steerage.....35 currency.

Prepaid Certificates, $36 currency.

LIVERPOOL SERVICE.

	Tons.	Master.	From Liverp'l.	From Philad'a.
"ABBOTSFORD,".....	2538.	Findlay.	Oct. 29.	Nov. 20.
"KENILWORTH,".....	2538.	Putt.	Nov. 12.	Oct. 23.

PRICES OF PASSAGE:

Cabin.....$100 gold.
Steerage.....30 currency.

Prepaid Certificates, $32 currency.

Tickets will be sold here at lowest rates, good from Antwerp and Liverpool to all interior points in the United States, *via* the Pennsylvania Railroad and its connections, thus affording parties in this country a convenient and cheap opportunity of sending for their friends in Europe.

THE RED STAR LINE will give special attention to the comfort of steerage passengers; comfortable berths, well-ventilated sleeping apartments and good food will be furnished them.

An experienced Surgeon is attached to each vessel.

Freight will be received at all principal points in the West and South, in connection with the Pennsylvania Railroad, Southern Mail Steam-hip Company and Clyde's lines, and through Bills of Lading issued for Antwerp, Bremen, Hamburg, Havre, Amsterdam, Rotterdam, Liverpool, London, Glasgow, Belfast, Hull and Leith.

The Red Star Line docks at Philadelphia are in direct connection with the Pennsylvania Railroad, and all merchandise intended for points beyond Philadelphia can be transferred from the hold of the steamer to the cars without the expense to shippers and risk of damage by re-handling, which results from cartage.

For rates of freight and passage, and other information, apply to

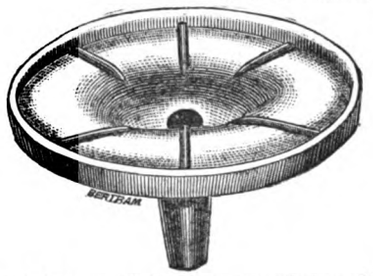
WATTS & COMPANY,

47 Holliday Street,
Baltimore, Md.,

SOLE MANUFACTURERS OF THE

PATENT CIRCUIT-CLOSER KEY,

Which has met with marked success.



Price, $5 50 plain $7; nickel-plated.

The following is from a competent judge, written after some weeks' trial.

145 BROADWAY, NEW YORK,
Sept. 22d, 1873.

DEAR SIR,—Your circuit-closing attachment on the key, left with me for trial, is pronounced by all who have used it a decided and much-needed improvement on the common form.

Respectfully,
A. S. BROWN, *Manager.*

The Best Form of Battery Insulator Offered.

SIMPLE AND PERFECT.

Made of porcelain, handsome in appearance. Occupies little more space than the cell it supports. Each cell of battery completely isolated. Leakage is reduced to the minimum by the use of it.

General Superintendent Van Horn, Southern Division W. U. Tel. Co., writes of it:

"We have now in use a thousand or fifteen hundred of your battery insulators, and expect to order many more before the close of the year.

We have never used any battery insulator that equals it in any respect. In fact, it appears to be as near perfect as we can reasonably expect, in a contrivance for that purpose."

Price 40 cents

We offer a very excellent article of Galvanized Wire, superior to any in the market. The linemen on Baltimore and Ohio R. R. say they have never seen its equal for toughness and flexibility.

Special attention given to building.

Estimates given for any amount of material for telegraph construction or extension.

SWITCHES, GALVANOMETERS, RESISTANCE COILS, &c., to order.

Designs for Switch Boards for special service furnished.

SCOTT'S PATENT ANNUNCIATOR,

for Hotels and Residences.

MANUFACTURE

Telegraph and Electrical Instruments

OF EVERY DESCRIPTION.

Facilities for supplying any description of Machinery or Material equal to any in the United States.

Patented Dec. 31, 1872.

Over SIX THOUSAND cells of the Baltimore Battery in use by the Gold and Stock Telegraph Company of New York in their Private Line Department, is a sufficient acknowledgement of its merit, as a form of the gravity battery, combining the valuable principles of

Economy, Cleanliness and Constancy,

"—in fact a base-burner."

F. L. POPE,
Telegrapher, July 5th, '73.

SELF-FEEDING,

No Sulphate of Copper can reach the Sulphate of Zinc Solution.

The shape of Zinc and Copper, which, with the tube, were patented December 31st, 1872, secures the largest surface with least weight of the metals. Half pound sulphate copper per month, ample supply for No. 2, or 3.

Following is one of the many letters we have from reliable telegraphers:

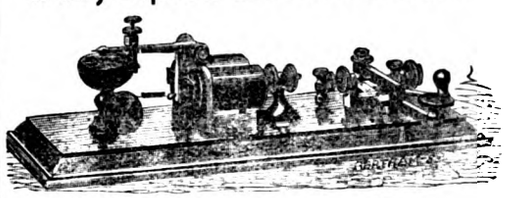
PIEDMONT, W. Va., September 28th, 1873.

Messrs. WATTS & Co.,
Baltimore, Md.

GENTLEMEN:—On January 1st, 1873, I put up 75 cells of your No. 2, Baltimore Battery, in place of 40 cells of carbon, from which two railroad wires of 100 miles each, are supplied. It has not since been taken down or cleaned, and has required no attention, except to fill the tubes with blue stone, once each month, and replenish the fluid once or twice during this period, made necessary by evaporation.

I am fully convinced, from long experience, that this is superior to any other form of the gravity battery.

It has now been in constant use for nine months, and will not need new zinc until after January next.



Respectfully,
J. G. NESBITT, *Manager.*

ORDERS FOR THIS BATTERY PROMPTLY FILLED.

A large stock constantly on hand.

No. 1 for Electro-motors, R. R. signals or similar service, $2.25
No. 2 ordinary local or Printing Telegraph main $1.75
No. 3 ordinary main $1.25

A very Superior Main Line Sounder.

Brass, $22.50. Nickel-plated, $25.00.

For wrecking purposes or temporary offices, this instrument is without a rival.

A perfect combination, handsome, good-sounding instrument.

NO LOCAL REQUIRED.

Well seasoned black walnut box, large enough for pencils, paper, plyers and office wire, in addition to the instrument, $4.

Larger size for climbers, vises, &c., $5.50.

RELAYS, SOUNDERS AND KEYS,

always on hand, plain or plated.

Our Challange Sounder is the noisest instrument made.

We furnish first-class goods at low prices. Liberal arrangements made with Superintendents, Contractors and Builders of Telegraph Lines.

Registers	$38 00	to	$45 00
Spring Registers	47 50		.....
Relays	14 00	to	18 00
Sounders	3 50	to	7 50
Keys	4 00	to	6 50
Main Line Sounders	14 00	to	18 00
Combination Sets	20 00	to	30 00

Galvanometers, $7 00 upward.

POCKET INSTRUMENTS, Nickel Plated, in Hard Rubber Cases, 1¼x2x5 inches.

CUT-OUTS, Plug, Peg or Button, with or without Lightning Arresters, for one, two or more Lines.

JONES' PATENT LOCK SWITCHES, the best and cheapest in use, with or without Lightning Arresters.

PEG or PIN, CULGAN, REPEATING, GROUND, LOCAL, BATTERY and SINGLE BUTTON SWITCHES.

LIGHTNING ARRESTERS for any number of wires, of most approved patterns.

Electro-Magnets,
Permanent Magnets,
Apparatus for Students and Amateur Telegraphers,
Electric Motors,
Printing and Dial Instruments
Electrical Annunciators,
Fire and Burglar Alarms,
Electro-Medical Instruments.

RHUMKORFF COILS, from ¼ to 10 inch spark.

GEISSLER'S TUBES, from $1.00 upward.

ELECTRICAL CALL AND ALARM BELLS in great variety, from $6.50 upward.

INSTRUMENTS furnished, Nickel Plated, at 20 per cent. advance on List Prices.

OFFICE WIRES, from 80c. to $1.25 per pound.

GUTTA-PERCHA COVERED WIRES, all sizes.

BISHOP'S NEW COMPOUND COVERED WIRE, for running into offices, 4c. per foot.

MAGNET WIRES, in Silk and Cotton, at Factory prices.

INSULATED WIRES for special purposes made to order.

SILK COVERED SWITCH CORD, one, two or more conductors.

PATENT MESSAGE HOOKS, the best ever introduced, prices 65c. and 75c. per dozen.

MANIFOLD PAPER and AGATE STYLUS at bottom prices.

Cables and Submarine Wires.
Repairers' Tools and Tool Bags.
Glass and Rubber Window Tubes.
Insulators of every Description.
Brackets, Pins and Spikes.

HILL, CALLAUD, GROVE, BUNSEN, CARBON, DANIELLS, LE CLANCHE, NITRO-CHROMIC, AND OTHER STYLES OF BATTERY IN ANY QUANTITIES.

PURE CHEMICALS AT LOWEST PRICES.

SULPHATE OF COPPER A SPECIALTY, AND PRICES VERY LOW.

CARBON PLATES made to order for Grenil, Smee, Stohrer and other Batteries.

OFFICE FIXTURES AND BATTERY UTENSILS OF EVERY DESCRIPTION.

Smith's Manual of Telegraphy," - - - - 30 cents.

ALL STANDARD WORKS on ELECTRICITY AND TELEGRAPHY.

SOLE AGENTS FOR

RICHARD JOHNSON & NEPHEW'S celebrated LINE WIRE.

Catalogue and Price List furnished on application.

L. G. TILLOTSON & CO.,

8 DEY STREET, NEW YORK.

F. L. POPE & CO.

Manufacturers and Dealers in

Telegraph Instruments and Supplies

OF EVERY DESCRIPTION,

38 Vesey Street, New York.

New and Superior patterns of

STANDARD TELEGRAPH INSTRUMENTS.

Their RELAYS, SOUNDERS, and KEYS which have been specially designed by Mr. F. L. Pope, are elegantly designed, thoroughly well finished and scientifically adapted to the service required and are recommended as SUPERIOR TO ANY HITHERTO OFFERED.

In addition to these ALL DESCRIPTIONS OF TELEGRAPH MATERIALS AND SUPPLIES are furnished, such as

INSULATORS, BATTERIES,
INSULATED WIRES,
CHEMICALS., ETC, ETC.

MAGNETIC AND DIAL INSTRUMENTS.

We have for sale also THE NONPAREIL TELEGRAPH INSTRUMENT for amateurs, learners and short lines.

A COMBINATION SET, comprising Sounder and Key on a handsome rosewood base.

Bradley's Box Relays and Sounders.
Bradley's Apparatus for Electrical Measurement.
Bradley's Naked Wire Helices and Magnet Spools to order, any desired size and resistance, at manufacturers' lowest price.

Descriptive Circular and Price Lists forwarded upon application to

F. L. POPE & CO.,

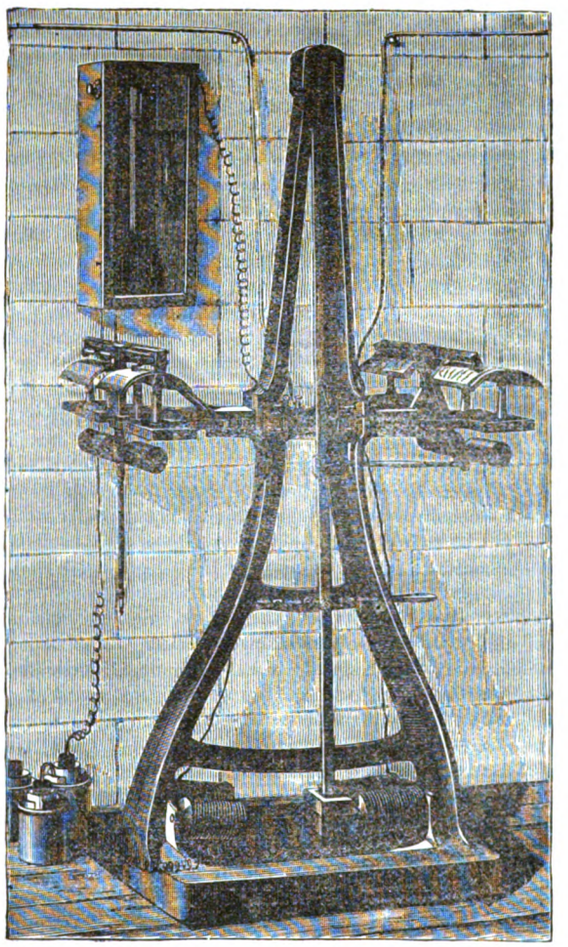
AUTOMATIC TELEGRAPHS.

CASELLI'S CHEMICAL COPYING TELEGRAPH.

The Abbe Caselli constructed a chemical copying telegraph in which he attained a synchronous movement in a somewhat surer way than by the methods adopted by either Bain or Bakewell.



His apparatus consisted of a long and heavy pendulum sustained in synchronous oscillation by the electro-magnet, and rocking, by means of a coupling bar, two metallic styles over the cylindrical stages.

The instrument consists of three principal parts—the motor, the copying style, and the time regulator. By reference to the illustration given, the different parts can readily be identified.

The pendulum rod is suspended from the top of an iron frame; the bob of the pendulum is constructed of iron and lead, the latter being employed for giving the necessary steadiness to the oscillations, and the former as armature for two fixed electro-magnets, one on each side at the foot of the frame.

The coils of these electro-magnets are connected with a local battery, and with a contact worked by the pendulum of a clock in the station, whose duty is not only to sustain the oscillations of the telegraph pendulums, but also to retain them, if need be, an instant, in order to re-establish their synchronism.

This motor is connected with the copying style by means of a rod between the pendulum rod and the end of a lever turning upon a pin in the axis of two cylindrical segments, or stages, and carrying upon its upper end the cross-beam. The latter carries on each side a fine screw, on which a nut rides, which carries the copying style. When the pendulum oscillates, therefore, an oscillating movement is imparted to the cross-beam, screw, and style, which cross and recross the surface of the cylindrical segments, or stages, following the movement of the pendulum rod. In order to avoid the styles passing twice over the same line, the screws by which they are carried end in ratchet-wheels, which, after every oscillation, are pushed round a tooth further, and thus draw the styles a given distance along in the direction of the cylinder. The styles consist of fine iron wires carried by guides in the electrical circuit. The styles are each only allowed to fall upon the cylindrical stages during oscillation in one direction, and as each apparatus carries two styles, one of them is down during the backward, and the other during the forward stroke. It is usual to receive on one side and to transmit on the other, by which a message may be received and one transmitted at the same time. On the side upon which the transmission is effected a leaf of metallic paper is fixed, upon which the despatch or design to be sent is written in insulating ink. When, therefore, the iron style passes and repasses over the surface, the current is interrupted during the time that a line of insulating ink is between the metallic surface and style. The reception, upon the other side, is done by means of a damp sheet of paper, impregnated with a solution of ferrocyanide of potassium. Under the influence of the galvanic current, this salt is decomposed, and forms, in contact with the iron style, a blue deposit, known as "Prussian blue." Thus, when the pendulum at the receiving station corresponds in its oscillations with that at the sending station, and both styles make the down stroke together, that of the reception marks the paper with a series of blue lines corresponding with the continuations of the line current given from the transmitter.

This telegraph was invented in 1856, but was not brought into a practical form until eight years afterwards. Froment, of Paris, succeeded in overcoming the mechanical difficulties which had until then opposed its progress. In 1865 two of these instruments were set up at work between Paris and Lyons, on which line they are still employed. The despatches sent by them are, however, of limited number, and are dearer, because they occupy more time, than those sent by the other method. In its operations, the Caselli telegraph, like all the copying telegraphs, is slow. Each line through which the style runs is 111$^{mm.}$ long, and occupies one second of time; and as the lines are 0·25$^{mm.}$ apart, therefore four seconds are necessary for every millimètre breadth of despatch. On a sheet of paper 111$^{mm.}$ by 27$^{mm.}$ about twenty-five words can be written, which therefore occupy 108 sec., or 1 min. 48 sec., in transmission—a speed which is exceeded only by the common Morse apparatus. Even if the back stroke of the pendulum be, at the same time, used for a return message, the speed is still very far below that of the Hughes instrument.

DECOMPOSITION BY ELECTRICITY.

It is wonderful to observe how small a quantity of a compound body is decomposed by a certain portion of electricity. Let us, for instance, consider this and a few other points in relation to water. *One grain* of water, acidulated to facilitate conduction, will require an electric current to be continued for three minutes and three-quarters of time to effect its decomposition, which current must be powerful enough to retain a platina wire, $\frac{1}{104}$th of an inch in thickness*, red hot, in the air during the whole time; and if interrupted anywhere by charcoal points, will produce a very brilliant and constant star of light. If attention be paid to the instantaneous discharge of electricity of tension, as illustrated in the beautiful experiments of Mr. Wheatstone†, and to what I have said elsewhere on the relation of common and voltaic electricity, it will not be too much to say, that this necessary quantity of electricity is equal to a very powerful flash of lightning. Yet we have it under perfect command; can evolve, direct, and employ it at pleasure; and when it has performed its full work of electrolyzation, it has only separa ed the elements of a single grain of water.

I showed in a former series of these Researches on the relation by measure of common and voltaic electricity, that two wires, one of platina and one of zinc, each $\frac{1}{18}$th of an inch in diameter, placed $\frac{5}{16}$ths of an inch apart and immersed to the depth of $\frac{3}{8}$ths of an inch in acid, con-

* I have not stated the length of wire used, because I find by experiment, as would be expected in theory, that it is indifferent. The same quantity of electricity which, passed in given time, can heat an inch of platina wire of a certain diameter red hot, can also heat a hundred, a thousand, or any length of the same wire to the same degree, provided the cooling circumstances are the same for every part in both cases. This I have proved by the volta-electrometer. I found that, whether half-an-inch or 8 in. were retained at one constant temperature of dull redness, equal quantities of water were decomposed in equal times in both cases. When the half-inch was used, only the centre portion of wire was ignited. A fine wire may even be used as a rough but ready regulator of a voltaic current; for if it be made part of the circuit, and the larger wires communicating with it be shifted nearer to or further apart, so as to keep the portion of wire in the circuit sensibly at the same temperature, the current passing through it will be nearly uniform.

† "Literary Gazette," 1833, March 1 and 8; "Philosophical Magazine," 1833, p. 204; "L'Institute," 1833, p. 261.

sisting of one drop of oil of vitriol and 4 oz. of distilled water, at a temperature of about 60° Fahr., and connected at the other extremities by a copper wire 18 ft. long and $\frac{1}{18}$th of an inch in thickness, yielded as much electricity in little more than three seconds of time as a Leyden battery charged by thirty turns of a very large and powerful plate electric machine in full action. This quantity, though sufficient if passed at once through the head of a rat or a cat to have killed it, as by a flash of lightning, was evolved by the mutual action of so small a portion of the zinc wire and water in contact with it, that the loss of weight sustained by either would be inappreciable by our most delicate instruments; and as to the water which could be decomposed by that current, it must have been insensible in quantity, for no trace of hydrogen appeared upon the surface of the platina during those three seconds.

What an enormous quantity of electricity, therefore, is required for the decomposition of a single grain of water! We have already seen that it must be in quantity sufficient to sustain a platina wire $\frac{1}{10}$th of an inch in thickness, red hot, in contact with the air for three minutes and three-quarters, a quantity which is almost infinitely greater than that which could be evolved by the little standard voltaic arrangement to which I have just referred. I have endeavored to make a comparison by the loss of weight of such a wire in a given time in such an acid, according to a principle and experiment to be almost immediately described; but the proportion is so high, that I am almost afraid to mention it. It would appear that 800,000 such charges of the Leyden battery as I have referred to above would be necessary to supply electricity sufficient to decompose a single grain of water; or, if I am right, to equal the quantity of electricity which is naturally associated with the elements of that grain of water, endowing them with their mutual chemical affinity.

In further proof of this high electric condition of the particles of matter, and the *identity, as to quantity, of that belonging to them with that necessary for their separation*, I will describe an experiment of great simplicity, but extreme beauty, when viewed in relation to the evolution of an electric current and its decomposing powers.

A dilute sulphuric acid, made by adding about one part by measure of oil of vitriol to thirty parts of water, will act energetically upon a piece of plate zinc in its ordinary and simple state; but, as Mr. Sturgeon has shown,* not at all, or scarcely so, if the surface of the metal has in the first instance been amalgamated; yet the amalgamated zinc will act powerfully with platina as an electromotor, hydrogen being evolved on the surface of the latter metal, as the zinc is oxidized and dissolved. The amalgamation is best effected by sprinkling a few drops of mercury upon the surface of the zinc, the latter being moistened with the dilute acid, and rubbing with the fingers so as to extend the liquid metal over the whole of the surface. Any mercury in excess, forming liquid drops upon the zinc, should be wiped off †.

Two plates of zinc thus amalgamated were dried and accurately weighed: one, which we will call A, weighed 163·1 grains; the other, to be called B, weighed 148·3 grains. They were about 5 in. long, and 0·4 of an inch wide. An earthenware pneumatic trough was filled with dilute sulphuric acid, of the strength just described, and a gas jar, also filled with the acid, inverted in it*. A plate of platina of nearly the same length, but about three times as wide as the zinc plates, was put up into this jar. The zinc plate A was also introduced into the jar, and brought in contact with the platina, and at the same moment the plate B was put into the acid of the trough, but out of contact with other metallic matter.

Strong action immediately occurred in the jar upon the contact of the zinc and platina plates. Hydrogen gas rose from the platina, and was collected in the jar; but no hydrogen or other gas rose from *either* zinc plate. In about ten or twelve minutes, sufficient hydrogen having been collected, the experiment was stopped: during its progress a few small bubbles had appeared upon plate B, but none upon plate A. The plates were washed in distilled water, dried, and reweighed. Plate B weighed 148·3 grains, as before, having lost nothing by the direct chemical action of the acid. Plate A weighed 154·65 grains, 8·45 grains of it having been oxidized and dissolved during the experiment.

The hydrogen gas was next transferred to a water-trough and measured; it amounted to 12·5 cubic inches, the temperature being 52°, and the barometer 29·2 inches. This quantity, corrected for temperature, pressure, and moisture, becomes 12·15453 cubic inches of dry hodrogen at mean temperature and pressure, which, increased by one-half for the oxygen that must have gone to the *anode*, i.e. to the zinc, gives 18·232 cubic inches as the quantity of oxygen and hydrogen evolved from the water decomposed by the electric current. According to the estimate of the weight of the mixed gas before adopted, this volume is equal to 2·3535544 grains, which therefore is the weight of water decomposed; and this quantity is to 8·45, the quantity of zinc oxidized, as 9 is to 32·31. Now taking 9 as the equivalent number of water, the number 32·5 is given as the equivalent number of zinc—a coincidence sufficiently near to show, what indeed could not but happen, that for an equivalent of zinc oxidized an equivalent of water must be decomposed.†

But let us observe *how* the water is decomposed. It is electrolyzed, *i. e.*, is decomposed voltaically, and not in the ordinary manner (as to appearance) of chemical decompositions; for the oxygen appears at the *anode* and the hydrogen at the *cathode* of the decomposing body, and these were, in many parts of the experiment, above an inch asunder. Again, the ordinary chemical affinity was not enough, under the circumstances, to effect the decomposition of the water, as was abundantly proved by the inaction on plate B; the voltaic current was essential. And to prevent any idea that the chemical affinity was almost sufficient to decompose the water, and that a smaller current of electricity might, under the circumstances, cause the hydrogen to pass to the *cathode*, I need only refer to the results which I have given to show that the chemical action at the electrodes has not the slightest influence over the *quantities* of water or other substances decomposed between them, but that they are entirely dependent upon the quantity of electricity which passes.

What, then, follows as a necessary consequence of the whole experiment? Why, this—that the chemical action upon 32·31 parts, or one equivalent of zinc, in this simple voltaic circle, was able to evolve such quantity of electricity in the form of a current as, passing through water, should decompose 9 parts, or one equivalent of that substance; and, considering the definite relations of electricity as developed in the preceding parts of the present paper, the results prove that the quantity of electricity which, being naturally associated with the particles of matter, gives them their combining power, is able, when thrown into a current, to separate those particles from their state of combination; or, in other words, that *the electricity which decomposes, and that which is evolved by the decomposition of, a certain quantity of matter are alike.*

But admitting that chemical action is the source of electricity, what an infinitely small fraction of that which is active do we obtain and employ in our voltaic batteries! Zinc and platina wires, $\frac{1}{18}$th of an inch in diameter and about half an inch long, dipped into dilute sulphuric acid, so weak that it is not sensibly sour to the tongue, or scarcely to our most delicate test-papers, will evolve more electricity in $\frac{1}{10}$th of a minute than any man would willingly allow to pass through his body at once. The chemical action of a grain of water upon four grains of zinc can evolve electricity equal in quantity to that of a powerful thunder-storm. Nor is it merely true that the quantity is active; it can be directed and made to perform its full equivalent duty. Is there not, then, great reason to hope and believe that, by a closer *experimental* investigation of the principles which govern the development and action of this subtile agent, we shall be able to increase the power of our batteries, or invent new instruments which shall a thousandfold surpass in energy those which we at present possess?—*Faraday.*

THE TELEGRAPH OF NATURE.

Look up to these clouds, these great water-carriers for a world, how joyously and jauntily they career along! The huge masses skip and whirl, and chase each other like lambs at play, neither wearied by the weight they bear, nor dizzy by the long look-down. Here, for once, is perfect engineering applied to water-supply. No retaining-walls are needed, and no windings to maintain the level. How softly they lie; how quickly they move; how gently they fall where they are needed, and when!

You are awakened out of your first sleep by the rattling at the casement, and a rumbling in the chimney. You rise and look out on the moon-lit sky; the cause of the nocturnal commotion is discovered at a glance. An interminable line of laden clouds, like a luggage train, each wagon heaped above its brim, is spinning eastward through the sky, from the Atlantic to the dry table-lands, on the confines of Europe and Asia. Those thirsty regions had telegraphed to their correspondent in the Western waters that the Caspian and Dead seas were in danger of becoming dry. The correspondent, ever watchful, and having withal a large stock in hand, newly distilled from the Atlantic, immediately dispatched an extraordinary night-train, with orders to run express all the way, "for the King's business required haste." There it goes frightfully quick, and with an infinity of imposing sound. But you may perceive it is running on the main line; the axletrees are well-greased, and the switches are all right. You tumble into bed again by way of shutting yourself into a siding, and sleep soundly till morning, confident that no collision will take place.—*Chicago Standard.*

An attempt was recently made at San Francisco to find the easterly current, and by its aid to reach New York by balloon in a few hours' time. The machine took a fine start, having on board three passengers, who, instead of finding the breeze they wanted, struck a westerly current and came down in the Pacific ocean, happily near the shore. The balloonists were received by boats and had a narrow escape.

* "Recent Experimental Researches," &c., 1830, p. 74, &c.

† The experiment may be made with pure zinc, which, as chemists well know, is but slightly acted upon by dilute sulphuric acid, in comparison with ordinary zinc, which during the action is subject to an infinity of voltaic actions. See De la Rive on this subject, "Bibliothèque Universelle," 1830, p. 391

* The acid was left during a night with a small piece of unamalgamated zinc in it, for the purpose of evolving such air as might be inclined to separate, and bringing the whole into a constant state.

† The experiment was repeated several times with the same results.

ACADEMY OF SCIENCE.

PHENOMENA OF GREAT STORMS—BY PROF. ELIAS LOOMIS.

This paper was described by title as "Some Results Derived from Examination of the United States Weather Maps."

The remarks I propose to make consist rather of a statement of what I am engaged in doing than of results which I am prepared to communicate. It is known to some persons that many years ago I undertook the investigation of certain storms, particularly Winter storms. Some 30 years ago I published in the transactions of the Philosophical Society of Philadelphia my investigations of a remarkable storm which was experienced throughout the United States in December, 1836. This storm of December, 1836, was followed a few days after by a remarkable storm in New York, and many conjectured at that time that there was a connection between the two storms; that the American storm crossed the Atlantic. Some years after, in 1856, I spent some time in Europe, and improved the opportunity to collect observations relating to this storm. I collected copies of meteorological journals for that period, and on my return undertook a new investigation of the phenomena of that storm, and of the American storm that preceded it. I have received maps regularly from the Department for about two years, and have preserved them carefully. I have thought it worth while, however, to undertake myself a systematic examination of these maps.

I first prepared a skeleton map upon precisely the same scale as the Washington maps, confining myself, however, to that portion of the country over which these storm tracks usually pass. Although these weather maps extend to the Pacific, the Department has never drawn isobaric lines extending beyond the Rocky Mountains with one exception, so that I was compelled to reduce the dimensions of my skeleton map, though retaining precisely the same scale. The first step consisted in transferring the tracks of all these barometric minima to this map.

The next step consisted in tabulating all these results. The lines on the maps are measured, and the dates and movements recorded in tables for two years. The direction of the storm track, and its motion per day, is indicated so that the tables show the progress in 24 hours of the barometric minima and their direction. He had complete tables for these months for two years. These tables, together, would show the average rate of progress of barometric minima and avorage direction. The average rate of progress each day for January was 680 miles; for February, 740 miles; for March, 940 miles; for April, 615 miles. The average for these four months was little less than 700 miles—a trifle less than 30 miles an hour. For the month of January the average direction of progress is 5 degrees north of east; that is the direction toward which the storm travels. It is very rare indeed that a storm travels toward the west, though we had one of that sort during the last week. There are only one or two decided cases of that kind in the period of two years. They almost invariably travel toward the east and a little north of east. For February the average is about 13 degrees north of east; for March, 11 degrees north of east; for April, 16 degrees north of east.

The object which I propose in this research will be to investigate the various circumstances which seem to cause these movements, the rate and the direction; to determine what other meteorological elements are connected with these. I tabulate with these numbers, therefore, a good many other points. One is a tabulation of what they call the "low," which means simply the lowest barometrical indication on the weather maps. Another is the fall in 24 hours—the fall of the barometer in that place where there is a "low." This is easily ascertained by consulting the map of the previous day at that place. The rise in the next 24 hours at the same place is found in the same way. Another element tabulated is the change of the "low." One day a "low" will be 29.4°; the next day it will be found some 500 miles east and perhaps will be 29.5° or 29.3°. It will not be generally stationary from one day to another. In other words, the storm will be increasing or diminishing in violence.

There is one point in regard to which he could make a somewhat precise statement. It is what might be called the stationary "low"; that is a stationary storm. In general, these storms travel with considerable velocity; occasionally we find examples of storms stationary for 24 hours, sometimes two or three days; there are examples of very violent storms remaining stationary for four days. The European storm of 1836 was the memorable storm of the century in its violence, which extended through Great Britain and all over the continent. At that time there was formed a "low" almost exactly over Switzerland, which continued stationary for four days, and the isobaric curves at that time were quite symmetrical and nearly circular, though slightly elliptical. The depression of the barometer at the centre of the storm was from a $\frac{1}{4}$ to $\frac{1}{2}$ of an inch below the average minimum.

Similar phenomena have been noticed since then in many instances in Europe. The localities where they have been most frequently observed are off the Irish coast, or somewhere along the coast line from the north of Scotland following down the English and French coasts to that of Spain. An average of notable cases of that sort were collated to the number of six or seven per annum, where the barometer sank very low and continued long at the same depression.

In examining the United States maps he had been struck with the circumstance that a storm traveling across the United States to Maine and New Brunswick would stop there, and the "low" be marked there for two or three successive days. There was no evidence whether the "low" proceeded beyond that point, as the map cannot give further information. However, by comparing these observations carefully it will be found that the actual height of the barometer at these most easterly stations continues the same during two or three successive days. Professor Loomis attributes this phenomena to local causes. These are probably the characteristics of the surface of the country—the high ranges of mountains which force the currents of air upward and cause condensation of moisture. In the case of Switzerland, this is occasioned by the Alps; in our country it is the high lands of Maine and the White and Green Mountain ranges. When there is a barometric minimum in that region, the air on the south side comes in from the ocean, and will be drawn in from considerable distances, probably from over the warm waters of the Gulf Stream.

DISCUSSION BY PROF. HENRY.

Prof. Henry suggested that if the storm comes to the seaboard the air is constantly drawn in from sea, bringing an immense amount of vapor. This may continue several days, constituting at Boston, for instance, a long and violent northeast storm, when 50 or 75 miles back in the country the air is clear. The storm appears to be produced by the heating of the lower strata and their expansion; then the epuilibrium being disturbed there is a rushing up of the moist air into a higher region, where it is condensed and the caloric given out, whereby the effect is increased. The whole storm is wafted eastward till it comes to the seaboard, where it obtains a continued supply. In the interior the supply at a given point is soon exhausted, and this may be a cause of the storm moving eastward. During a storm at the seaboard there is a motion outward; the wind is blowing inward from the ocean below, but outward toward it above. Great interest attaches to the investigations which Prof. Loomis is making.

LEGAL PAR IN STERLING EXCHANGE.

A long-needed law passed the last Congress, intended to eliminate from all accounts with Great Britain the confusion and obsolete fiction of 9½ per cent., miscalled "exchange." By an old law the Custom-House valuation of the pound was $4.44. Owing, however, to a change in the relative value of the precious metals, the gold in the pound had come to be worth a little over $4.86, or about 9½ per cent. more than the legal valuation. But in all the accounts, and in all the tables, the old legal valuation, $4.44, is first assumed, and then the 9½ per cent. is added to correct the error. It has no more to do with "exchange" than the mariner's allowance for deviation of the compass needle has to do with a correct observation of the sun's altitude.

The 9½ per cent. added to the wrong valuation makes the right one, and then the real rate of exchange is expressed by the fluctuations of one or two per cent. around that point. Thus exchange now called 111 is really only at 1½ per cent. above par; and at 108 it is about 1½ below par.

But Congress now wipes out the old fictitious valuation, and establishes the correct one, and after January next the 9½ per cent. will cease to encumber the tables of exchange and every money calculation between the United States and England. We reprint the principal section of the law, as follows:

In all payments by or to the Treasury, whether made here or in foreign countries, where it becomes necessary to compute the value of the sovereign or pound sterling, it shall be deemed equal to four dollars eighty-six cents and six and one-half mills, and the same rule shall be applied in appraising merchandise imported where the value is, by the invoice, in sovereigns or pounds sterling, and in construction of contracts payable in sovereigns or pounds sterling; and this valuation shall be the par of exchange between Great Britain and the United States; and all contracts made after the first day of January, 1874, based on an assumed par of exchange with Great Britain of fifty-four pence to the dollar, or four dollars and forty-four and four-ninths cents to the sovereign or pound sterling, shall be null and void.

Beside the gain in simplicity and intelligibleness in all our international accounts, there will be one result of this change that will be peculiarly gratifying to Americans. Assuming that Great Britain accepts the correction and adjusts her quotations accordingly, all our securities will thenceforth be quoted, on the average, 9½ per cent. higher than now. When our five-twenties are worth par they will be so quoted in England, and not at 91, as heretofore. And, as English quotations are a sort of standard for Europe, there will be eventually a higher appreciation of credit and financial rank of the United States among the nations.

MM. Tréve and Chedeville find that if a current of electricity traverses a coil of wire that surrounds a cooling ingot of cast steel, the steel, when perfectly cold, shows on fracture a finer grain than when the current is not passed. The magnetized steel also had less power of resisting forces of extension and compression.—*Scribner.*

THE SIGNAL SERVICE.

The connection of the Signal Service with the lines of telegraph throughout the country renders its operations more or less important to all engaged in telegraphic service. The annual report of the Chief Signal Officer has just been published, from which we glean as follows :

Systematic and continuous instruction of the army in military signaling and telegraphy during the past year has been given at the Signal School of Instruction at Fort Whipple, Va., and in the Department of the Missouri. The recommendation made in previous reports, that special instruction at the Military Academy should be provided for, with a merit value given it, affecting the standing of the cadets, is renewed, and it is also suggested that to secure accuracy and uniformity, the officer to be in future charged with that instruction should have passed through the course at Fort Whipple.

Six commissioned officers have received instruction at Fort Whipple during the year. Sixty-seven private soldiers have been instructed as candidates for promotion to the grade of observer-sergeant, and 127 as assistants to observer-sergeants.

The whole number of stations from which the office now receives its stated meteoric reports is 92, of which 78 are the regular stations in the United States ; 11 are in Canada ; three in the West Indies. Of the stations in the United States, 13 have been added during the year ; and of the Canadian, from which reports have been received by comity of exchange with the Dominion Meteorological Bureau, four are new. The regular telegraphic reports from Havana, Cuba, began on August 6 ; from Kingston, Jamaica, on September 18, and from Santiago de Cuba on September 29. Three other points in the islands of Porto Rico, Guadaloupe, and Barbadoes, will be equipped as soon as observers can be designated.

The total number of tabulated bulletins issued and distributed at the several lake, seacoast, and river ports and inland cities has been 143,097, excluding the river bulletins of changes in depth of water of principal rivers. The total number of weather charts issued and distributed has been 320,770, and the press reports (exclusive of the publication of the synopsis and probabilities) have been 23,224. Nine thousand four hundred and two copies of "the weekly weather chronicle" and 6,896 of the "monthly weather review" have been furnished and gratuitously distributed to the press, agricultural and commercial associations, institutions of learning and scientific persons.

The office has, under the direction of the Secretary of War, continued its exertions to solve, for the special benefit of the agricultural interests, the problem of giving promptly the information contained in the daily weather reports to the many farming and other communities not now reached by telegraph, and for which the copies published by the press do not arrive in time for use. The plan adopted has been to divide the territory of the United States into districts, each district having a distributing point at or near the centre, from which two printed copies of the Synopses and Probabilities are forwarded by mail to all post-offices within the districts, and which can be reached by rail, steamer or mail coach by 4 P. M. of the same day. This plan has been put in operation with the co-operation of the Post-office Department, the bulletins being exhibited in frames by each postmaster at each post-office as soon as received, and now provides for the regular distribution daily of 8,982 printed copies of the Weather Report, for display at 4,191 different post-offices.

For the study of the phenomena of the upper portions of the atmosphere, in view of the benefit of the deductions to be had from them, and to determine more accurately the proper reductions to be made for great elevations, stations have been established at favorable points. In addition to those on Mount Washington, N. H., and on Mount Mitchell, N. C., the difficult task of establishing a permanent telegraph station on the summit of Pike's Peak, at an elevation of 14,216 feet, has been accomplished with the sanction of the Secretary of War. A telegraph line has been built to connect the station with Colorado Springs, and it is now in operation.

The ascertained comparative accuracy of the deductions from reports, styled "Probabilities," has been more clearly presented in this than in preceding years. The percentage of verification has been mathematically computed for each of the geographical districts mentioned in the reports. The annual average of verifications has been as follows for the following named districts :

New England, 81.50 ; Middle States, 81.17 ; South Atlantic, 79.92 ; Lower Lakes, 78.90 ; Eastern Gulf, 77.16 ; Ohio Valley, 76.42 ; Western Gulf, 74.40 ; Upper Lakes, 75.25 ; North West, 74.00.

An additional duty was imposed upon the Secretary of War by the legislation of the last Congress, authorizing the establishment of signal stations at lighthouses and at such of the life-saving stations on the lake or sea coasts as may be suitably located for that purpose, and to connect the same with such points as may be necessary for the proper discharge of the duties of the Signal Service by means of a suitable telegraph line, in cases where no lines are in operation. In discharge of this duty, a telegraph line has been completed, ten miles in length, from Seaville to Peck's Beach, N. J., connecting at Seaville with the line of the Western Union Telegraph Company. The material is ready, and the work is in progress on the construction of a line from Sandy Hook to Barnegat Inlet, N. J., a distance of 50 miles, connecting with the Western Union line at Long Branch. These connections will allow of signals being displayed at the life-saving stations established at Sandy Hook, Long Branch, Barnegat, Atlantic City, Peck's Beach and Cape May. The plan in contemplation proposes the establishment of signal stations at life-saving stations and lighthouses along the ocean coast of New Jersey, from Sandy Hook to Cape May, at distances of 25 miles from each other. A line is in process of erection from the village of Rockport, Mass., to Thatcher's Island Lighthouse, a distance of three miles and a half, of which one mile and a half will be cable. A line connecting the stations at life-saving stations and lighthouses along the coast, from Norfolk, Virginia, to Cape Hatteras, North Carolina, a distance of 137 miles, and on one of the most dangerous coasts of the United States, is in construction. It is expected that the above-mentioned lines will be completed during the present year. Attention is invited to the fact that the whole work now done in the erection of these lines, and to be done hereafter in operating them, has been done, and is to be done, by the officers and men of the Signal Service of the army.

The Chief Signal Officer refers to the proceedings of the Meteorological Congress of Vienna, held in pursuance of invitations officially issued by the Austrian Government, for a convention of persons charged with meteorological duties in different countries. The adoption, by the unanimous vote of the Congress, of a proposition to the effect that it is desirable, with a view to their exchange, that at least one uniform observation, of such character as to be suitable for the preparation of synoptic charts, should be taken and recorded daily and simultaneously at as many stations as practicable throughout the world, is regarded as of special importance in reference to works of the kind now undertaken by the United States. This formal announcement, with such sanction, tends directly to the establishment of systems of signals and weather reports common among civilized nations.

Arrangements have already been made with Russia and Turkey to begin, on January 1, 1874, the exchange with the United States of one daily report, taken simultaneously at the different stations throughout the great territorial extent of the Russian and Turkish Empires and the United States. The co-operation of the systems of other nations is expected.

DETERMINATION OF ORGANIC IMPURITIES IN WATER.

Water, even though free from color and an appreciable odor and taste, and at the same time furnishing a proper lather with a small proportion of soap, may yet have sewage impurities sufficient to render its use extremely dangerous. The *Pharmaceutical Journal* quotes from Heisch a very simple and important test for determining the quality of drinking water, and especially as to its freedom from sewage contamination. This consists in placing a few grains of the best white lump-sugar in half a pint of the water in a perfectly clean, colorless, glass-stoppered bottle, freely exposed to daylight in the window of a warm room. If the water be perfectly free from sewage contamination, it should not become turbid, even after an exposure of a week or ten days, in which case it is almost certainly safe, otherwise not.

A Million Dollar Telescope.—In a recent address before the California Academy of Sciences, Professor George Davidson made the following remarks—words which we are sure will find their way to every quarter of the civilized world, and engender the liveliest pleasure to every lover of science and her advancement : "With a telescope of the largest size and most consummate workmanship that American skill can devise, properly located ten thousand feet above the sea, in the clear skies of the Sierra Nevada, with every variety of apparatus commensurate therewith ; with masters of observation and ingenuity in research ; with ample funds reserved to devise other instruments and methods which those instruments and the highest genius must suggest, we hope, at no distant day, to see solved the mighty problems of creation that are yet beyond our grasp. Such an outfit and such provision have been the lifelong objects of James Lick ; and after much earnest solicitation, I have overcome his shrinking from what he considers vain glory, and obtained his permission to announce to the Academy his intentions, which I have faintly sketched in the preceding sentence. There will be no let or hindrance in carrying out his views ; the amplest means are provided; the rarest skill has been invoked, and the plans are taking definite and practical shape."

The *Mining and Scientific Press*, of San Francisco, of which city Mr. Lick is one of the wealthiest denizens, notes that the scheme, as already indicated by Professor Davidson, is being quietly perfected, and that the geological, meteorological and other peculiarities of various sites of the mountain range above named are soon to be carefully scrutinized and reported upon. A peak will be selected which, from its high altitude and clear surrounding atmosphere, will afford the finest possible view of the heavens throughout the longest period of the year, and there the observatory will be permanently located.

HOW THE PENNSYLVANIA COMPANY REGULATES TIME.

(From the Toledo Blade.)

The Pennsylvania Company, in the extensive ramifications of its railroad interests, extending largely eastward and westward, has necessarily experienced some embarrassment on account of the difference of time. This may be clearly understood and appreciated when we state that the difference between Chicago and Pittsburgh time is about thirty minutes, and in order to ensure safety in running trains and avoid confusion in the general business, a common time is necessary for the entire system controlled by the Company. Those least conversant with railroad matters can see this at a glance. Accordingly, Columbus time has been adopted as the standard time of the road, but heretofore, although all clocks of the Company have approximated that time, there have been more or less variations, which seemed next to impossible to avoid. To obviate the difficulty, and secure exact correspondence of time throughout the whole extent controlled by them, the officers of the Company have lately adopted and carried into successful operation a system of telegraphic time signals, which we will endeavor to explain:

A telegraphic circuit has been established between the clock of the Allegheny Observatory and the general offices of the Company at Pittsburgh. The observatory is under the management of Prof. S. P. Langley, a well-known scientist of eminent qualifications, and who, it will be remembered, was selected by the Government, two years ago, to direct an expedition into Spain to observe the eclipse of the sun, and investigate various matters in the interest of astronomical science. Professor Langley regulates the clock of the Observatory by astronomical observations, and the pendulum of the clock is so connected with the circuit that the latter is broken and closed at each vibration, and thus regular pulsations of seconds are transmitted over the wire and sounded upon a bell in the telegraph rooms of the general offices. At any time during the day or night the bell may be switched in, and the standard clock corrected to within an infinitessimal part of a second. The arrangement of the mechanism at the Observatory is such that the seconds are beat consecutively until the forty-ninth, inclusive; there is then a pause (closed circuit) of five seconds, followed by a beat of four seconds, then a pause (closed circuit) on the fifty-ninth second, and a beat on the sixtieth second, completing the minute. The pauses are considered as preliminary signals for comparison with clocks, and the beat on the sixtieth second indicate the point where the exact difference can be noticed.

The time is transmitted over all lines of the Company at four P. M. of each day, as follows;

At 3:55 P. M. the operator at Pittsburg signals "Time," (business being suspended on the circuits for ten minutes for the purpose of sending time), and by a number of repetitions of the word "Time" attracts the attention of all operators, near and remote, on the circuits. At or about 3:57 he connects the main lines by automatic repeaters with the Observatory circuit. After such connection is made, the second beats are repeated on the main circuit until 3:58, at which time the mechanism of the Observatory clock opens the circuits and holds them open for one and a half minutes, or until thirty seconds before 4 o'clock. The circuits are then automatically closed and vibrations of seconds return on the thirty-first second. The first pause (closed circuit) of five seconds thereafter, as before described, calls attention to the approaching completion of the minute, and the first beat which follows the pause on the fifty-ninth second, gives the stated hour sharp.

By this process exact Columbus time is transmitted each day, and clocks regulated at Pittsburgh, Mansfield, Crestline, Fort Wayne, Chicago, Toledo, Erie, Ashtabula, Dennison, Columbus, Cincinnati, Indianapolis, Vincennes, Richmond, Ind., Bradford, Logansport, Zanesville, Lancaster and intermediate points. Each division is supplied with a good clock, which is carefully regulated by Observatory time, and with which conductors and employees are instructed to compare their time daily.

Wm. Thaw, the Vice-President of the Company, and Prof. Langley, have been very active in the promotion of this object, and to these gentlemen, seconded by the officers of the departments interested, its complete success is due.

THE AURORA.

The aurora has long been regarded as a mysterious phenomenon, subject to no law, and too capricious to be associated with other appearances. But within the past few years physicists have discovered a certain periodicity in displays of auroræ, and that the grandest occur at intervals of about sixty years. Since then attempts have been made to show a dependence between auroræ and sun-spots, or to connect them with phenomena of magnetism, both of which, as many readers are aware, have an eleven-yearly period of maxima and minima. Professor Loomis, of Cambridge, U. S., who has well considered the question, says, in a recently published paper, we are not to suppose that a black spot on the sun exerts any direct influence on the earth's magnetism or electricity, but that the spot is evidence of some disturbance on the sun's surface, which instantly affects the earth's magnetism, and occasions a flow of electricity wherein the auroral light is produced. It may be that there is a direct flow of electricity from the sun; and if light and heat are the result of vibrations of a rare ether which fills all space, electricity may be assumed to be similarly produced, or to be at least a force capable of being propagated through the ether with a velocity equal to that of light. While traveling through the void celestial spaces, it develops no light; but as soon as it meets the earth's atmosphere, which appears to extend to a height of five hundred miles, it then does develop light, and its movements are controlled by the earth's magnetism, in a manner analogous to the influence of an artificial magnet upon a current of electricity circulating round it.

Thus, we may provisionally accept, as the latest theory on this interesting question, the conclusion that there is some relation between the mean daily range of the magnetic declination and the number of auroræ observed, and that these phenomena, again, are related in some way to the appearance of spots on the sun. It is a theory which may well engage the thoughts of all who take interest in the progress of physical science.—*Chambers' Journal.*

In a paper by Dr. A. H Garrod, the following ingenious hypothesis regarding the production of Nerve Force is advanced. Admitting that the force in question is either identical with, or closely allied to, electricity in its properties, he then asks, where does it originate? The existence of special organs for its development in the torpedo and other creatures which exhibit external electrical phenomena, and the absence of any such organ in man and the higher animals, would seem to indicate that the production of electrity in animals requires some other form of apparatus than the nervous ganglia. In answer to this, the Doctor seeks to show that, in the difference of temperature between the interior and surface of the living body, a source of energy is presented which, on thermo-electric principles, is capable of producing all the force required. The brain and minor ganglia, he adds, would then act as offices for the reception and transmission of currents in the required directions, being in fact the commutators of the system.

In support of this the Doctor says: "There are several of the most important phenomena exhibited by the nervous system which are very satisfactorily explained on the above hypothesis. For instance, in cold weather the impulse to action is much more powerfully felt than in Summer, when the air is hot, and therefore the temperature of the surface is higher. It is well known that it is impossible to remain for more than a very short time in a hot-water bath of which the temperature is as high as, or a little higher than that of the body, on account of the faintness which is sure to come on, and this may be reasonably supposed to be the result of the cessation of the nerve-current, which is consequent on the temperature of the surface of the body becoming the same as that of the interior. This faintness is immediately recovered from by the application of a cold douche. When great muscular exertion has to be sustained, as in swimming or rowing, it is always necessary to have the clothes very thin, and it is felt during the time that it is necessary for the continuance of the effort that the surface of the body must be kept cool."—*Scribner's.*

A letter from Nordenskjöld, the Arctic explorer, dated Mussel Bay, Spitzbergen, September 9, 1872, giving an account of some interesting observations on the presence of iron dust in the atmosphere, has just been published in "Comptes Rendus," from which we translate as follows: In December, 1871, there occurred the heaviest fall of snow of which we have any record. It snowed incessantly for five or six days, and many lives were lost in the capital. Supposing that the impurities floating in the atmosphere would be brought down with the snow of the first two days, I waited till the storm was over, and then collected, with all due care, a quantity of the superficial snow and melted it, with a view to ascertain whether it contained any solid matter. To my great surprise I observed that this snow had a large amount of black sooty dust, consisting of an organic substance rich in carbon. This substance is of the same nature as the meteoric dust which fell simultaneously with meteorites, properly so called, at Hessle, near Upsal, on the 1st of January, 1868.

It is just possible that the carbonaceous matter came from the chimneys of Stockholm and the metallic iron from the roofs of the houses, most of which are of iron in that city. Still, considering the matter as one worthy of study, I wrote to my brother, Carl Nordenskjöld, who lives far away from cities, in the interior of Finland, and who takes an interest in meteorology, and asked him to repeat my experiment. After having removed the chief causes of error, and collected the snow in a plain surrounded by forests, he too found a black dust, which he sent to me. Analysis showed that it was of the same nature as that of Stockholm, and from both the magnets extracted particles which were recognized as metallic iron.

In St. Andrew's Church, Dublin, an excessive reverbertion of sound has been checked by stretching wires across the building.

ELECTRICITY AND DEATH.

Lecture before the London Society, by BENJAMIN W. RICHARDSON, M. A., M. D., F. R. S.

The object of the lecture was to put forward certain facts the author had learned on the phenomenon of muscular irritability after systematic death. He included in the same study certain examples in which muscular irritability has for a time ceased, but has become re-developed under new conditions. He thus included the study of those states which favor the continuance of irritability or which destroy it, and those conditions which suspend it, but do not destroy it. By this the effect of electrical excitation is in the same direction, but is varied according to the mode in which the excitation is performed. Discharge from the Leyden jar produces contraction, which is permanent or intermittent in accordance with the mass of the muscle and the intensity of the discharge. This fact was elucidated by reference to a series of experiment with a Leyden battery, placed in cascade, and the effect produced by the discharge from 96 feet of surface upon animals of different sizes and weights, from sheep down to pigeons, as well as on sections of the bodies of the same animals immediately after death. The experimental facts demonstrated that with an efficient discharge the whole muscular system of a small animal could be fixed instantly in the rigidity of death, and that the precise position of the animal at the period immediately preceding death was retained with such perfection, so sudden was the change, that nothing but physical examination by the hand could bring to the mind the fact that the animal had passed from life into death.

But the same shock passed through a sheep weighing 54 pounds produced only a temporary contraction of muscle, and required repetition before the rigidity was rendered permanent.

By employing discharges of less tension, it was found that muscles, or special tracts of muscles, in the same animal immediately after its death, could be made rigid quickly or slowly by variation of the intensity of the discharge.

The effect of the intermittent electro-magnetic current was next brought forward, and was shown to resemble closely that of the simple electrical discharge from the Leyden phial.

Intensified, it induces permanent contraction ; and if it be repeated even with low tension, so as to call forth contraction, it destroys the irritability, *cæteris paribus*, more quickly than if the muscle had been left to itself.

Parenthetically, the lecturer dwelt here on the common practice, after sudden death, of endeavoring to excite the action of the enfeebled heart by passing through it an electrical current. Some practitioners, said the author, have gone so far as to introduce a needle into the heart itself, and to make the needle act as one of the conductors from a battery. Such experimentalists, before they undertake this operation on the human subject, should at least observe the effect of the agency they are employing on the exposed heart of an inferior animal recently and suddenly killed by drowning or by a narcotic vapor. They would learn then with what infinite facility the muscular irritability of the heart, in all its parts, is excited for a moment only to be permanently destroyed. They would learn that, if blood be not passing through the muscular structure concurrently with their exciting current, they could not more effectually arrest function than by the very method they have adopted to sustain it.

The influence of the continuous current on muscular irritability was introduced by the author, together with a special reference to the first experiments of Aldini on the bodies of malefactors who had been recently executed ; and it was shown from Aldini's most noted experiment how largely the phenomena of motion he induced in a dead man, and the recital of which caused so much sensation in the year 1803, was due, not to the galvanism, but to the circumstance that the dead body had been exposed for the hour after death and before the experiments commenced, to the action of cold 2° below freezing point. On the whole, the continuous current acts on muscular fibre after the manner of heat. If the muscle, recently dead, be exposed to cold, the current, when sufficient, restores, for a limited period, the irritability, and finally destroys it by inducing persistent contraction. If the muscle, recently dead, be left at its natural temperature, the current shortens the period of irritability by quickening contraction.

ELECTRO-MUSIC REPORTER.

A novel application of electricity to musical instruments for the purpose of recording the inspirations of genius in musical compositions, is now in process of construction for Mr. C. T. Shelton, of New Haven, Conn. It is a telegraphic attachment to an organ. Beneath each note of the three manuals and of the pedals, and connected with each stop of the organ, is a small brass spring, which is pressed down whenever the piece to which it is attached is brought into action. From each spring, wires run to a galvanic battery of twelve cells, and to the recording apparatus, which may be situated at any convenient distance from the organ. When the spring is pressed down, connection between the battery and the recording apparatus is formed, and the electric current passes through. The recording apparatus is very simple, and similar to that used in Morse's telegraph. Attached to the clockwork, by which a uniform motion is produced, are two cylinders some eighteen inches in length, between which is carried a strip of paper divided into about 250 longitudinal divisions—one for each note and stop in the organ. Corresponding to each of these divisions is a magnet whose armature carries a lever armed with a style, which indents the paper as long as the electric current is passing through. Now, when any note or stop is brought into action the spring connected with it is pressed down, the circuit is completed, the corresponding armature is attracted to its magnet, and the division of the paper belonging to the note struck is indented with a line proportionate in length to the time during which the note is held down. A staccato touch will be represented by a simple dot, while a longer tone will be recorded by a more prolonged indentation. The clockwork is so geared that the paper is carried forward on the rollers at the rate of about one half an inch per second, thus recording each note in the most rapid playing at the rate of about ten notes per second by a line one twentieth of an inch in length, and longer notes by lines proportionally extended.—*Scientific American.*

THE delay in the completion of the West India and Panama system is a notable disappointment. Two of the cables have already been repaired by the steamer Investigator, but the line between Martinique and Dominica—a distance of forty miles—is still bridged over by a schooner service. This, with the delay on the Cuba section, interferes with the perfect organization of the rich traffic which unquestionably awaits the complete opening out of the West Indian system. Another adverse event of the month has been the check in perfecting the first section of the Brazil cable. The expedition to submerge the second section of this line from Madeira to St. Vincent left the Thames about the 14th ult., and the work is expected to be completed before the close of the year.

SEVERAL geese died in Mormon Island, Cal., a few days ago, and, upon dissection, gold dust was discovered "in fatal quantities" in their gizzards. And yet there was no suspicion that either of these was the golden goose we hear so much about.

AMERICAN INVENTIONS IN ENGLAND.—The Midland Railway of England is fitting up four trains, including fourteen Pullman cars, with Olmstead's electric brake, which Mr. W. B. Chapin is introducing. The cars are also fitted with Miller platforms, and with the Allen paper wheels, which have Krupp's crucible steel tires, costing, it is said, £20 each. The electric brake, it is said, is being tried on the Southwestern and North British lines, and will be tried on roads in France, Russia, Austria, Norway and South America. It was used for some time in this country on the Chicago, Burlington & Quincy and Providence & Worcester roads, though we believe that it has been improved somewhat of late.

How can I make an electro-magnet to be operated by an earth battery ? Answer : You can make an earth battery by sinking two large plates of copper and zinc in moist earth, and connecting them by conducting insulated wires attached to each. Such a battery was constructed by Bain in 1841. You can make an electro-magnet by winding stout copper wire, covered with silk, around a piece of soft iron bent in the form of a horse shoe, care being taken that the coils are wound in the same direction around each bobbin, either from or towards the axis of the magnet. The more numerous the coils, and the greater the power of the electric current, the stronger the magnet.

THE Lexington Avenue Synagogue is lighted by induced electricity, produced by a new frictional apparatus and condenser, contained in one small case. The electricity, generated by turning a crank, is stored up in the condenser, which, when a sufficient quantity and intensity is arrived at (depending upon the number of burners to be lighted), is discharged, producing a spark at each burner—the circuit being there broken—and ignites the gas which has been turned on immediately before the discharge.

THE Brazilian Submarine Telegraph Company have announced a postponement of the opening of the Lisbon and Madeira section of their line. The cable was laid between Lisbon and Madeira on the 19th of September, but the section proved imperfect, owing to the development of a fault. On the 26th ult. the cable, in an attempt to recover it, was broken, and owing to the subsequent continual bad weather and loss of grapnel rope, the contractors have for the present ceased further operations.

IT is announced in the *Buenos Ayres Standard* that the great event in Uruguay was the opening (which took place on the 12th September last) of the land lines of the Brazil and River Plate Telegraph Company (Companhia Telegraphica Platino Brazileira), represented in London by Messrs. Grant Brothers & Co., of Lombard street. The lines were working most successfully, the first day's messages having amounted to the satisfactory number of 120, which considerably exceeded the expectations of the company.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 BROADWAY, NEW YORK,
December 1, 1873.

To all Offices on W. U. Lines:

The following additions and changes have been made since the date of the last Circular:

GENERAL INFORMATION.

Coopers, Ala., closed.
Wilhites, Ala., closed.
Marianna, Ark., re-opened.
* Fort Yuma, Arizona.... 100 8 San Diego, Cal., check San Francisco.
* Marcicopa Wells, Arizona..... ....100 8 " "
* Phœnix, Arizona.....100 8 " "
* Prescott " .....100 8 " "
* Wickenburg " .....100 8 " "

Offices will enter the points in Arizona named above on page 5 of the tariff book.

Aptos, Cal., closed.
Boca, Cal., re-opened.
Maine Prairie, Cal., closed.
Menlo Park and Mountain View, Cal., are now W. U. offices.
Mokelumne Station, Cal., changed to Lodi.
San Luis Ranch, Cal., closed.
Vaca Station, Cal., changed to Elmira.
Yountville, Cal., re-opened.
East Killingly and Northford, Conn., closed.
Malad, Idaho, re-opened.
The P. O. A. of Lynn, Ill., is Lynn Centre, Henry Co.
Lima, Ind., closed.
Port Allen, Iowa, closed.
De Soto, Ks., closed.
Petersburg, Ks., changed to Kinsley.
West Point, Ky., closed.

On and after December 8, Bangor, Me., will be in square 11, instead of 10 as heretofore.

Plane No. 4, Md., closed. Business will hereafter be sent and checked to Mt. Airy.
Ashland, Md., closed.
Cockeysville, Md., closed.
Phenix Sta., Md., closed.
Cohasset, Mass., closed.
North Adams, Mich., closed.
Como, Miss.. re-opened.
Glenbrook, Nev., closed.
Deep Creek, Nev., closed.
Kingston, N. B., closed.
Wortendyke, N. J., closed.
The P. O. A. of State Line, N. Y., is Northville, Erie Co., Pa.
East Hampton, L. I., N. Y., closed. Messages are delivered from Sag Harbor, L. I. Charges for delivery, $3 special, or 25 cents by stage.
Hereafter, business for Gorham, Pine Valley, and Starkey, N. Y., will be sent via Canandaigua, N. Y., only.
Abbottsburg, N. C., reopened, square 116.
Cartwrights, Oregon, closed.
Estes Ranch, Oregon, closed.
Grant's Pass, Oregon, closed.
Marion Sta., Oregon, closed.
Milwaukee, Oregon, closed.
Bear Valley, Pa., closed.
Moorheads, Pa., closed.
Torresdale, Pa., closed.
Clinton, Lawrence Co., Pa., closed.
Business for Port Royal, S. C., will hereafter be checked direct.
Ophir, Utah, closed.
Martinez, Utah, closed.
Monticello, W. T., closed.
Kidders Camp, W. T., closed.
English Camp, W. T., closed.
Hatt's Camp, W. T., re-opened.

NEW OFFICES.

The following revised list of offices and tariffs of the Marietta and Cincinnati Telegraph line has been received:

The rate for additional words is the same as that on W. U. Lines.	Cincinnati, O. 233	Chillicothe, O. 213	Marietta, O. 181	Portsmouth, O. 213
Cumminsville	25	50	60	60
Blanchester	40	50	60	60
Big Run	60	50	30	60
Greenfield	50	30	60	60
Hamden	60	40	50	50
Hillsboro	75	85	95	
Jackson, Jackson Co.	60	40	50	40
Leesburg	50	40	60	60
Frankfort	50	30	60	50
Londonderry	60	30	50	50
Lynchburg	75	85	85	
Maderia	30	50	60	60
Madisonville	30	50	60	60
Martinsville	40	40	60	60
Mineral City	60	50	40	50
Monroe Furnace	60	50	60	40
New England	60	50	40	50
New Vienna	50	40	60	60
Raysville	60	:0	50	50
Scott's Landing	60	50	25	60
Sciotoville	50	40	60	25
Vincents	60	50	30	60
Webster	60	50	60	30
Zaleski	60	40	50	50

The "tariff for this line," for offices in Indiana, Kentuck, and West Virginia, on business to or from Quebec and Ontario should be 85 and 6, not 85 and 5, as given in JOURNAL of August 15th, 1873.

SPECIAL RATE OFFICES.

The tariff to Treverton, Pa., is 25 cents more than "special rate" to Philadelphia, and to Milwaukee Stock Yards, Wis., same as "special rate" to Milwaukee.

ATLANTIC CABLE BUSINESS.

We are notified of the following change in rates on Atlantic Cable Business.

	For 10 words.	For 20 words.
Aden—(Messages above 10 words are charged the 20 word rate)	$10 00	$15 00
Greece via Falmouth		4 75
Candia—Canea, Retimo via Falmouth and Corfu		6 38
Japan—Hiogo, Osaka, Simonosaki, Yeddo or Yokohama via Falmouth, Teheran or Siberia		42 62
———Ditto, if written in Code or Cypher		44 88

Ceylon via Falmouth or Teheran, $10.50 for 10 words and $1.05 for each additional word.

India—West of Chittagong, including Kurrachee via Falmouth or Teheran, $10. for 10 words and $1. for each additional word.

India—East of Chittagong via Falmouth or Teheran, $10.50 for 10 words and $1.05 for each additional word.

On Messages to China and Japan, the words "Via Siberia," when inserted, must be charged for beyond London.

CUBA CABLE BUSINESS.

We are notified, that the words "Care of Nunes," may hereafter be dispensed with as part of the address in messages intended for transmission by the Colon (Aspinwall), Cable.

In messages destined for points reached by that Cable, but not intended to be forwarded by telegraph beyond Jamaica, the words, "Post Jamaica," must be inserted and charged for.

WILLIAM ORTON, *President.*

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is over 8,000. It goes to every State, Territory and Province on the Continent. It has become a necessity, and is always welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, DECEMBER 1, 1873.

THE POSTMASTER-GENERAL'S REPORT.

Whatever may be Mr. Cresswell's merits, his treatment of the Postal Telegraph scheme in his coming report will not elevate the public conception of his fitness for his high trust. The extract from it now before us, indeed, fills us with a surprise almost sorrowful. We venture to say, that, as a public document, it will be found unique in its weakness, a weakness which its author will be made to feel. Instead of the calm argument of fact and policy which a State officer, taking an unimpassioned view of the circumstances of the nation, is expected to employ, and which, when stated with dignity and justice, never fails to elevate the tone of public sentiment with respect to the general administration of public affairs, we have a personal, infelicitous, and what appeares to us, vindictive attack upon the Western Union Telegraph Company, and its chief executive officer. Nor is this apparent vindictiveness less prominent than its inaccuracy. Its statements are, indeed, so incorrect, and that, too, in the face of the most easily ascertained facts, as would, in ordinary circumstances, challenge, on our part, the pity of silence, but which, coming from such a source, seems to ask a word of notice at our hands.

In the extract before us the report opens with the following words: "The Western Union Company has always contended for high rates, and enforced them with a high hand." Now, this is alike untrue and sensational. What does Mr. Cresswell mean by enforcing rates "with a high hand?" Are there degrees of administration by which the hand of authority is heightened or depressed? Is it a "high hand" which demands three cents for a posted letter, and casts it back if unpaid? Mr. Cresswell must pardon us, but the expression sounds to us like that of a man irritated by opposition to a pet personal conceit, and alike undignified and sensational. It seems used with a design to express the existence of a power in the way of public justice. And yet no one knows better than Mr. Cresswell that in the matter of rates, the policy of the Western Union Company has been one of steady and rapid reduction. The average message to-day is only half the amount of six years ago. The policy of the Company is now, and always has been, to establish such a basis of rates, as shall make every charge strictly just to the public, and yet affording a fair return to those whose capital has provided the lines. Mr. Creswell may deny the truth of this, yet it is strictly correct, and the proof thereof is ready and abundant.

Here is another extract, so incorrect as to be simply puerile:

"When new associations have been formed for the purpose of reducing rates, the Western Union Company has at once entered the lists to destroy its rivals, and in pursuit of victory has not scrupled to use any device which the powerful can employ against the weak. Failing to vanquish its adversary in the open field of fair competition, it has resorted to artifice, and triumphed by making gold its weapon. Thus it has acquired, by lease or purchase, lines of the American Telegraph Company, the Illinois and Mississippi Company, the Chicago and Mississippi Company, and the California State Company, and during the past year it has obtained control of the International Ocean and Pacific and Atlantic Companies."

Now, those who know the relations of all but two of the companies named, and which are thus stated as having been originated to reduce rates, and against which the Western Union Company is represented as "entering the lists," low rates in one hand and gold in the other, to destroy them, will smile at the amazing ignorance thus exposed. Aside from the Chicago and Mississippi and Pacific and Atlantic companies, every other company named was originated, has always acted in concert with, and as the regular connections of the Western Union Company, and in no sense and never in opposition. They occupied entirely distinct territory. They were united by common consent to secure uniformity of administration and directness and cheapness of transmission. As to the exceptions named, the Chicago and Mississippi Company occupied a limited territory on the north of Missouri, and the control of the Pacific and Atlantic was accomplished by voluntary personal offers of stock by large holders on terms which commended the purchase, and in which no pressure whatever was to the least degree employed. These are facts which were within Mr. Creswell's power to obtain from sources which would have been freely opened to him. They are, indeed, mainly facts of general public knowledge. Ignorance of them in the preparation of a great national paper on so grave a theme seems, at least, extraordinary.

Is it any use to follow a document which in its few opening lines commits such huge affronts on intelligence and truth? We venture to say that, with no wish to disparage Mr. Creswell, no public paper has appeared for many years, if ever, which has, at least in the treatment of this matter, so exposed its author to public rebuke. It will fall, as all such presentations fall, by the gravity of its own weakness, burying with it the whole scheme it was written to subserve, and that, too, with sadly attenuated hopes of any speedy resurrection. For ourselves we deeply regret the publication of such a report. It detracts from the dignity of public station. It soils the ermine of administration. It disturbs the respect which should encircle official position. Surely this vast nation does not need and does not deserve such aid to accomplish designs officially presented as necessary to the public weal.

In answer to inquiries, we are sorry to state that the Editor of the JOURNAL, Mr. Grace, has been confined to his house, Scotch Plains, N. J., for the past six weeks or more, by an injury caused by a fall, from which, however, he is rapidly recovering.

ST. JOHNS, N. F., Nov. 21.—The telegraph cable steamer "Robert Lowe," the property of the Anglo-American Telegraph Company, was lost near St. Shotts, St. Mary's Bay, on Wednesday, November 19. The chief officer and two boats' crews were saved. The captain's and two other boats are missing. The tug steamer "Cabot" has been dispatched to assist the missing boats.

THE success of Stearns' Duplex Telegraph in Europe widens, as we knew it would wherever its merits were honestly canvassed and a fair opportunity given to prove its value.

We now learn that Mr. Stearns has arranged for a Duplex line between London and Amsterdam, and which is no doubt already in operation. In December, the Duplex will be applied to the line between London and Paris. About the same time it will be connected with the main lines in Belgium and in Austria.

In *Meteorological Science* it is probable that an epoch of great importance has been reached in the unanimous agreement of the congress which was in session at Vienna from the 2d to the 15th of September as to the importance of taking at least one synchronous observation of the weather daily at all possible stations throughout the entire world. It will be seen that this idea, if successfuly carried into effect, is but a grand extension of the system of tri-daily synchronous observations which has been in operation for three years in the Army Signal-office. The result arrived at in the Vienna congress is to a considerable extent due to the efforts of Brigadier-General Albert J. Myer, Chief Signal-officer, U. S. A.

AN editor, of course, is supposed to know everything, but, if he is to die outside a lunatic asylum, he ought to be protected against the propounders of questions like this: "A strong man is suddenly struck dead by lightning. What has become of the potential energy he possessed before he was struck?" The editor so cruelly assailed was equal to the occasion; but have any of our readers sufficient potential energy to unriddle the mystery for themselves? We doubt it, and, giving them the benefit of that doubt, beg to inform them that his potential energy would be where it was before—within the space bounded by his external surface! What the lightning has done, has been to destroy the mechanism for its realization. A small portion of the man's potential energy might have been converted into actual energy by the lightning, as, for instance, in the shape of heat; but the great bulk would be got by anybody who chose to eat his body. How potential energy must accumulate amongst canibals! We have heard some odd apologies for man-eating, but Sidney Smith himself could scarce have bettered this scientific justification of a weakness for cold missionary.

EXECUTIVE OFFCE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, Nov. 25th, 1873.

Gen. ANSON STAGER,
Gen. T. T. ECKERT,
JNO. VAN HERNE,
JAMES GAMBLE,
Gen'l Supts.

On Thursday the 27th inst., on Thursday December 25th, and on Thursday, January 1st, office hours will be from 8 to 10 o'clock A. M. and from 4 to 6 P. M., except at repeating stations and at principal offices, which will be kept open as usual, but with such reduction of force on duty, as circumstances may permit.

WM. ORTON,
President.

OTHER LINE BUSINESS.—OFFICIAL.

Notices of non-collection of charges upon "collect" messages originating at other line offices, and office messages in regard to special delivery charges upon messages to or from other line offices, should always be addressed to the CONNECTING office, and not direct to the other line office.

Notices of non-delivery, and requests for better address, should, however, always be addressed direct to the ORIGINATING office.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Nov. 22, 1873.

On December 1st, Virginia City, Mont., in W. B. Hibbard's district, will be closed as a money order office.

CORRECTION.

For *Greensbury, Pa.*, in last issue of JOURNAL, read *Greensburg, Pa.*

G. H. MUMFORD, Vice Pres't.

CHARLES HOWARD, the absconding telegraph operator at the Sylvan Lake Mines, Beekman, N. Y., took the steamer for England, and will probably be arrested on the other side.

We regret to have to announce the death of the wife of Mr. C. H. Summers, Electrician of the Central Division of the Western Union Telegraph Co., November 22d, at Highwood, Illinois.

THE JOURNAL OF THE TELEGRAPH will commence its Seventh Volume with the issue of January 1, 1874. The price of subscription will be $2. Particulars will be given in our next.

Subscribers to Vol. VI. will receive the December numbers without extra charge.

The lists of deaths in the ranks of men of science has recently been unprecedentedly large. We have before mentioned those of Professors Coste and J. Chacornac, and now add to them Professor Donati, director of the Astronomical Observatory at Florence, who died of cholera on the 20th of September at Vienna, and Professor Czermak, an eminent physiologist, who died at Leipsic on the 18th of September. The latter is well known for his special physiological researches, and particularly by being in great part the inventor of the laryngoscope.

A SUM of money is voted annually by Parliament for scientific instruction in the United Kingdom; the object of the grant being to promote instruction in science, especially among the industrial classes, by affording a limited and partial aid or stimulus towards the founding and maintenance of science schools and classes. The following are among the sciences towards instruction in which aid is given: Acoustics, Light, Heat, Magnetism and Electricity: Inorganic Chemistry, Organic Chemistry, Geology, Mineralogy, Mining, Metallurgy.

FOR TARIFF BUREAU CIRCULAR see page 391.

A large amount of matter has been crowded out of the present number.

DURING the late cash panic sale at Claflin & Co.'s, New York, the number of telegraph messages sent and received at the Claflin branch office was 629. Total amount of business done, $583.75.

WE are glad to welcome the *Popular Science Monthly* on the list of our exchanges. In comeliness of form, in typography, in the high field it occupies, and the manner of its occupation, it is an honor to our current literature, and challenges a large support.

ELECTRIC APPARATUS FOR INDICATING LEAKAGE IN SHIPS.—Sortais has devised an electrical apparatus to be placed in the hold of ships for the purpose of giving warning in case of a leakage. On the entrance of the water a current is established, and notice thus given to the officers.

THOSE who have delicate galvanometers should be careful to see that they are not kept in the field of permanent magnets, unless, as in the case of the mariner's compass, they are free to move in the direction of the lines of forces of the magnetic field in which they lie, otherwise they will quickly lose their magnetism. (W. H. Preece.)—*Scribner.*

IN Marshall, Texas, out of 78 cases of yellow fever, 62 died. A large portion of the population fled, leaving few behind, except the sick. Of the 16 who recovered, was operator M. M. Bond, who informs us that Supt. L'Hommedieu nobly risked his life by waiting upon him and others during their illness, and, in the absence of clergymen, performed the burial services at the graves of the dead. God will honor all such true men.

MM. TOMMASI and MICHEL propose a new method of pneumatic telegraph for parcels. In place of driving the boxes containing the parcels by compressed air they propose the use of ammoniacal gas. By the action of heat on aqua ammonia at one end of the tube the ammonia is evolved, and by its pressure urges the box forward; at the same time, by the action of cold water at the opposite end of the tube, the ammonia in front of the tube is absorbed, a vacuum produced, and the parcel acted on by traction as it were. The tube being always full of ammonia, and the same supply being used over and over, it is supposed that a sufficient economy in working pneumatic tubes may be obtained to render their general introduction possible.

DEATH OF A WELL KNOWN TELEGRAPH OPERATOR.—Intelligence has been received of the death, from pneumonia, on the 10th inst., at St. Louis, of Mr. C. W. Hill, a well known telegraph operator, who was stationed in Baltimore in 1870, as manager of the Insulated line from Boston to Washington, the building of which Mr. Hill superintended from New York to Washington. Although but thirty-seven years of age, he had been twenty years in the service of the Western Union Telegraph Company up to 1868. He was one of the oldest operators, and one of the best. He leaves a wife and three children, who reside in Baltimore. Mr. Hill was a native of Rochester, New York, and his remains will be brought here for interment.—*Baltimore Sun*, Oct. 14, 1873.

NOTES AND QUERIES.

Suppose we should take in a message of twelve words at 50 and 3; total, 56c. Should we collect 55c. or 60c.?

Answer in JOURNAL, *Nov.* 1.—Collect 56c.

Now, "down South" we have no change smaller than 5c. Please be a little more explicit in next number of your JOURNAL, as cases of this kind are of frequent occurrence with us.

Very truly yours,
R. T. RAOUL, Operator.

Answer.—The Company requires 56 cents from you. You will have to charge 60 cents to make yourself whole. We would have answered thus had the case been fully stated at first. Still, there is this to be said: No just man would take advantage of this and charge the same person twice in the same manner. There is usually a way of adjusting these things equitably. The right is clear to average charges, so as to protect yourself.

DOMINICK, N. Y.—In receiving a message over the counter, directed "John Smith, Squillville, N. Y., by mail or train from Syracuse, N. Y., should any part of the address be counted? If so, how many words in the above address?

Answer.—Practice has allowed the addition to the address above given as a part thereof. Postage, of course, has to be added to tariff and stated in check.

TAWAS CITY, Mich., Nov. 7, 1873.—Suppose a message was sent from Tawas City, Mich., to Maustin, Wis., via Chicago, at half rate, charge by this line to Chicago 38c., and 30c. for other line. Bay City, Mich., a repeating office, refused to accept of message unless full rates were paid; message was sent after 7 P. M.; then I only asked half rate to Chicago, and other line will be paid full rate, and the last was refused. Was Bay City right in refusing to accept the message at half rate? Answer through your columns, and oblige,

Yours respectfully,
A. DE PERWINOFF, *Manager.*

Answer.—The facts are these. Maustin, Wisconsin, is an office of the Northwestern Telegraph Co. That company refuses to do half-rate business. The Western Union Co. does no half-rate business on messages going to other lines which do not transmit on half rates. You, therefore, were in error in accepting the message on any terms short of full rates for both lines.

Bay City had, strictly speaking, no right to arrest a message on its transit. Had he, however, accepted it, you would have been called upon to pay the difference by the Chicago office.

Please inform me, in your next issue, the number of ohms required in good relays, to work in a circuit of six and 100 miles of line, in order to work with a small battery power?

Answer.—About 100 ohms.

Supposing a message is received at our office with no better address than Mr. John Dunn, he being a stranger and address not known to us. Should we send a boy to inquire at the two hotels (within office limits), or wait and send for better address from originating office? Two "Oprs" had a dispute about this and would like an answer in JOURNAL.

Ans.—Much is necessarily left to the good sense of managers. If sending a messenger to two hotels within office limits could effect delivery, it would, of course, save time to the line and its recipient. Yet, in receiving such a message from an originating office direct, a full address should have been asked. We think offices accepting such messages should be reported.

Digitized by Google

TELEGRAPHERS' MUTUAL LIFE INSURANCE ASSOCIATION.

ACKNOWLEDGEMENT OF RECEIPTS FOR ASSESSMENTS NOS. 47 AND 48, UP TO NOVEMBER 20.

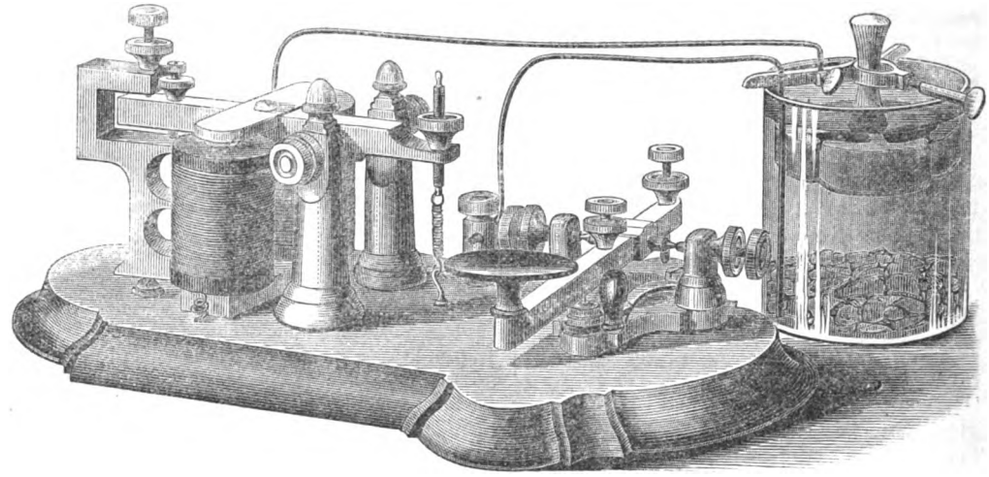
25, 42, 44, 69, 185, 186, 187, 274, 294, 347, 425, 515, 692, 695, 697, 700, 705, 766, 842, 996, 1071, 1134, 1135, 1136, 1204, 1208, 1277, 1278, 1279, 1368, 1400, 1439, 1504, 1515, 1556, 1557, 1570, 1609, 1613, 1669, 1670, 1710, 1722, 1726, 1727, 1741, 1742, 1778, 1779, 1807, 1808, 1815, 1827, 1848, 1854, 1916, 1929, 1930, 1938, 1945, 1946, 1947, 1948, 1967, 1968, 2016, 2018, 2025, 2038, 2063, 2064, 2066.

ASSESSMENTS NOS. 49, 50, 51 AND 52.

4, 6, 13, 16, 26, 44, 52, 54, 55, 56, 60, 61, 64, 70, 74, 86, 89, 98, 99, 111, 122, 129. 133, 134, 141, 142, 143, 144, 146, 148, 153, 154, 156, 157, 158, 160, 164, 169, 175, 181, 183, 188, 189, 190, 191, 193, 197, 198, 200, 211, 213, 217, 218, 228, 235, 244, 245, 255, 257, 267, 269, 274, 276, 278, 279, 280, 281, 282, 283, 285, 301, 302, 311, 312, 319, 323, 341, 344, 346, 349, 351, 352, 353, 361, 378, 381, 383, 391, 394, 402, 405, 406, 413, 416, 425, 426, 430, 434, 438, 456, 467, 478, 509, 510, 526, 532, 533, 536, 548, 549, 554, 574, 575, 576, 577, 579, 586, 587, 597, 600, 603, 622, 630, 642, 646, 655, 662, 663, 664, 665, 669, 670, 672, 678, 680, 698, 703, 708, 714, 721, 723, 724, 728, 731, 740, 742, 750, 751, 756, 758, 769, 772, 775, 780, 787, 791, 799, 806, 808, 812, 823, 830, 831, 832, 842, 855, 858, 870, 873, 876, 883, 897, 901, 911, 917, 938, 942, 943, 954, 956, 957, 959, 960, 963, 964, 976, 978, 979, 991, 992, 995, 1001, 1005, 1009, 1011, 1013, 1024, 1039, 1040, 1046, 1054, 1055, 1061, 1073, 1074, 1075, 1076, 1081, 1085, 1102, 1139, 1148, 1154, 1155, 1156, 1157, 1159, 1160, 1162, 1164, 1167, 1169, 1173, 1174, 1185, 1195, 1200, 1204, 1210, 1211, 1221, 1222, 1225, 1226, 1227, 1228, 1232, 1234, 1235, 1237, 1238, 1240, 1245, 1248, 1251, 1252, 1259, 1260, 1267, 1268, 1270, 1271, 1276, 1282, 1287, 1288. 1292, 1294, 1295, 1300, 1303, 1304, 1325, 1327, 1333, 1343, 1353, 1354, 1355, 1368, 1371, 1376, 1402, 1403, 1404, 1407, 1410, 1417, 1418, 1425, 1440, 1444, 1448, 1451, 1453, 1454, 1455, 1456, 1482, 1498, 1505, 1506, 1507, 1508, 1515, 1517, 1519, 1522, 1523, 1527, 1535, 1537, 1542, 1554, 1555, 1558, 1560, 1563, 1564, 1568, 1569, 1571, 1572, 1579, 1582, 1590, 1597, 1593, 1594, 1615, 1623, 1630, 1631, 1632, 1634, 1635, 1644, 1646, 1648, 1652, 1656, 1659, 1660, 1661, 1662, 1663, 1665, 1667, 1681, 1682, 1684, 1687, 1688, 1696, 1697, 1707, 1709, 1710, 1713, 1719, 1720, 1721, 1723, 1724, 1728, 1730, 1732, 1733, 1745, 1749, 1765, 1766, 1767, 1773, 1775, 1788, 1789, 1791, 1803, 1815, 1817, 1830, 1831, 1839, 1840, 1841, 1843. 1844, 1845, 1847, 1852. 1860, 1867, 1868, 1869, 1872, 1882, 1903, 1906, 1911, 1913, 1914, 1915, 1916, 1919, 1926, 1938, 1942, 1943, 1950, 1951, 1959, 1965, 1968, 1970, 1987, 1991, 1996, 1997, 1998, 1999, 2000, 2001, 2016, 2021, 2024, 2026, 2027, 2028, 2029, 2033, 2035, 2036, 2040, 2041, 2059, 2060, 2061, 2065, 2072, 2074, 2075, 2079, 2083, 2084, 2086, 2089, 2093, 2094, 2096, 2098, 2099, 2106. 2110, 2111, 2116, 2133, 2135, 2136, 2138.

MISCELLANEOUS.

No. 49—28, 42, 711, 1626. *No.* 50—28, 42, 277, 463, 516, 711, 1626, 1629, 1818, 2020, 2131. *No.* 51—28, 131, 277, 463, 516, 553, 711, 859, 874, 932, 1626, 1629, 2017, 2020, 2073, 2082, 2131. *No.* 52—28, 131, 277, 286, 463. 516, 553, 859, 874, 932. 1178, 1626, 1629, 2017, 2020, 2073, 2119, 2131.



CATCH HIM!

CAIRO AND VINCENNES RAILROAD,
CAIRO, Ill., Nov. 15, 1873.

On Thursday, November 6, an operator, named Frank Finley, absconded from Vienna, on Cairo and Vincennes Railroad, with two hundred dollars of Company funds. The said Finley is a fair, sound operator, with general good appearance, and likely to deceive; has light hair, light-blue eyes, light, thin moustache and red, full cheeks; is about 5 feet 7 inches in height, and probably 23 years of age; had on, when last seen, dark-brown frock coat, dark vest and light pants, well worn. Any information, leading to his arrest, will be liberally paid for.

J. A. PATTERSON, *Supt. Tel. Co.*

IF a person eats between meals, the process of digestion of the food already in the stomach is arrested, until the last which has been eaten is brought into the condition of the former meal; just as, if water is boiling and ice is put in the whole ceases to boil until the ice has been melted and brought to the boiling point, and then the whole boils together. But it is a law of nature that all food begins to decay after exposure to heat and moisture for a certain time. If a meal is eaten, and in two hours another, the whole remains undigested for seven hours, before which time the rottening process commences, and the man has his stomach full of carrion—the very idea of which is horribly disgusting.

PARTRICK, BUNNELL & CO.'S

Champion Learners' Instruments.

COMBINED No. 1 SOUNDER AND KEY, with
BATTERY, OFFICE WIRE, CHEMICALS, and a thorough
BOOK of PRACTICAL INSTRUCTION in the Art of Telegraphy

Which latter gives all necessary directions for setting up the Battery and complete apparatus, and operating them for practising or communicating purposes.

THIS IS WARRANTED TO BE, BEYOND ALL COMPARISON, THE BEST APPARATUS EVER OFFERED FOR THE USE OF STUDENTS OF TELEGRAPHY.

Being excellent Morse instruments, substantially made and nicely finished, with nothing left out of their construction which pertains to a Complete Sounder and Key Combination Set. Nothing made in miniature, or in awkward and unusual shape, as is done with the very cheap affairs usually offered as Learners' Apparatus. They are equally well suited

For TELEGRAPHIC SCHOOLS OF INSTRUCTION, For PRIVATE TELEGRAPH LINES, and
For CITY WIRES OF TELEGRAPH COMPANIES.

The BATTERY which accompanies the Learners' Outfit is a full-sized Callaud, the same as the best cells used by Telegraph Companies for main battery, and gives sufficient power to produce a loud, clear sound from the instrument, the Sounder of which embodies the same remarkable principles of sound which have made our "Giant Sounders" so famous and popular among telegraphers.

The BOOK OF INSTRUCTION is a clear and practical explanation, by an experienced telegrapher, of every fact and principle of modern telegraphy and its apparatus which a student of the art could possibly require to obtain, in undertaking to become an accomplished sound operator.

PRICE OF APPARATUS complete, with Book of Instructions, Battery, Wire, and all necessary materials for one complete office outfit, ready for shipment, $10, sent by Express, C. O. D.; or $9.50, if money order for that amount be sent in advance. The latter plan will additionally save the purchaser the Express charges for returning money.

PARTRICK, BUNNELL & CO.,
38 South Fourth Street, Philadelphia.

The *London Telegraphic Journal* announces a professional Almanac, to be called *the Telegraphic Journal Almanac*, and which was to appear Nov. 15th.

The steamship Hooper has started with 1,500 miles of cable to be laid from Pernambuco, where it will be joined up with the section just laid to Bahia, and from Bahia to Rio de Janeiro. At the latter point the Hooper cable will be coupled up with the Plato Brazillian Company's line, which company will lay a cable from Rio to Maldonado. From the latter point the Montevidean Company will lay a cable to Montevideo, which will be united to the Buenos Ayres cable to Valparaiso.

MARRIED.

BURGOON—MOUSE.—Sept. 23, at Johnstown, Pa., by Rev. Gallagher, Frank J. Burgoon, manager W. U. Tel., Conemaugh, Pa., to Miss Maggie Mouse.

MCCARTY—CARPENTER.—November 11, 1873, at the residence of the bride's parents, in Bullitt County, Ky., W. O. B. McCarty, bookkeeper W. U. Telegraph Office, Louisville, Ky., to Miss Rhoda A. Carpenter, of Bullitt County, Ky.

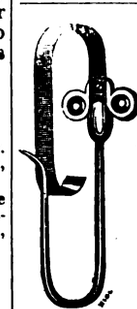
BORN.

BUSKIRK.—To J. S. Buskirk, operator D. L. and W. R. R., Orange, N. J., November 2, a son.

DIED.

COX.—In Batesville, Panola Co., Miss., on Thursday, November 13, of typhoid fever, William A. Cox, manager W. U. Tel. Co.

SECOND-HAND RELAYS.



A large lot of well polished and good working Relays for sale cheap.

Also several sets of

THE SERVICE.

CALIFORNIA DIVISION.

SAN FRANCISCO, Nov. 14, 1873.—The following appointments, transfers and resignations have taken place in this Division since date of last report:

Appointments.—Thos. R. Sheridan, Albany, Or.; Miss Weidman, Petaluma, Cal.; C. H. Boynton, Sacramento, Cal.; C. W. Gearhart, Stockton, Cal.; Thos. McMicken, Dayton, Nev.; W. F. Cox, Cherry Creek, Nev.; J. K. Ellis, Gordon's Station, Cal.; T. F. Holland, Vallejo, Cal.; G. R. Stanton, Stockton, Cal.; A. Hebberling, Dayton, Nev.; L. L. Williams, St. Joseph, Or.; H. Scheld, Trinity Centre, Cal.; F. W. A. Crain, Eugene City, Or.

Tranfers.—W. T. Hunter, Bakersfield, Cal., to Visalia, Cal.; W. T. Hunter, Stockton, Cal., to Bakersfield, Cal.

Resignations.—G. W. Richards, Albany, Or.; G. R. Stanton, Reno, Nev.; C. H. Boynton, Reno, Nev.; C. D. Ellis, Stockton, Cal.; A. Hebberling, Dayton, Nev.; F. P. Lee, Virginia, Nev.; C. W. Johnston, Dayton, Nev.; J. W. Kelly, St. Joseph, Or.; J. E. Murray, Trinity Centre, Cal.; A. V. Peters, Eugene City, Or.

Yours truly,

JAMES GAMBLE, *Gen'l Sup't.*

ALFRED CORNU has recently made an experimental determination of the velocity of light. The rate of movement obtained is 189,200 miles per second in a vacuum. This agrees very closely with the result obtained by Foucault by a different method in calculating the parallax of the sun. This number gives the value 8″.86, which agrees with that obtained recently by M. Leverrier; it must, therefore, be accepted as being very near the true number.—*Scribner.*

RED STAR LINE.

ANTWERP SERVICE.

APPOINTED TO CARRY THE BELGIAN AND UNITED STATES MAILS.

		From Antwerp.	From Philad'a.
"VADERLAND," Captain Vander Heyden,	2800 tons.	Nov. 12.	Oct. 22.
"RYDAL HALL," Captain Collin,	2114 tons.	Oct. 11.	Nov. 5.
"NEDERLAND," Captain H. W. James,	3000 tons.	Oct. 25.	Nov. 22.
"SWITZERLAND," Captain ——,	3000 tons.	Building.	

PRICES OF PASSAGE:

Cabin.....$100 gold.
Steerage.....85 currency.

Prepaid Certificates, $36 currency.

LIVERPOOL SERVICE.

	Tons.	Master.	From Liverp'l.	From Philad'a.
"ABBOTSFORD,".....	2538.	Findlay.	Oct. 29.	Nov. 20.
"KENILWORTH,".....	2538.	Putt.	Nov. 12.	Oct. 23.

PRICES OF PASSAGE:

Cabin.....$100 gold.
Steerage.....80 currency.

Prepaid Certificates, $32 currency.

Tickets will be sold here at lowest rates, good from Antwerp and Liverpool to all interior points in the United States, *via* the Pennsylvania Railroad and its connections, thus affording parties in this country a convenient and cheap opportunity of sending for their friends in Europe.

THE RED STAR LINE will give special attention to the comfort of steerage passengers; comfortable berths, well-ventilated sleeping apartments and good food will be furnished them.

An experienced Surgeon is attached to each vessel.

Freight will be received at all principal points in the West and South, in connection with the Pennsylvania Railroad, Southern Mail Steamship Company and Clyde's lines, and through Bills of Lading issued for Antwerp, Bremen, Hamburg, Havre, Amsterdam, Rotterdam, Liverpool, London, Glasgow, Belfast, Hull and Leith.

The Red Star Line docks at Philadelphia are in direct connection with the Pennsylvania Railroad, and all merchandise intended for points beyond Philadelphia can be transferred from the hold of the steamer to the cars without the expense to shippers and risk of damage by re-handling, which results from cartage.

For rates of freight and passage, and other information, apply to

PETER WRIGHT & SONS,

GENERAL AGENTS, PHILADELPHIA.

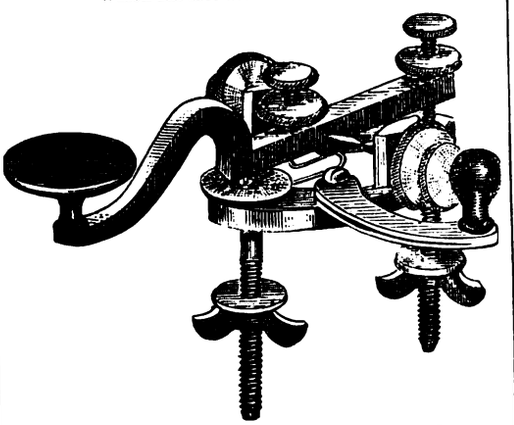
WATTS & COMPANY,



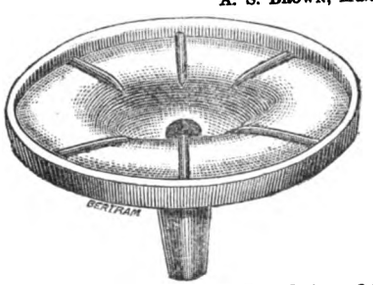
47 Holliday Street,

Baltimore, Md.,

SOLE MANUFACTURERS OF THE

PATENT CIRCUIT-CLOSER KEY,

Which has met with marked success.



Price, $5 50 plain $7; nickel-plated.

The following is from a competent judge, written after some weeks' trial.

145 BROADWAY, NEW YORK,
Sept. 22d, 1873.

DEAR SIR,—Your circuit-closing attachment on the key, left with me for trial, is pronounced by all who have used it a decided and much-needed improvement on the common form.

Respectfully,
A. S. BROWN, *Manager.*

The Best Form of Battery Insulator Offered.

SIMPLE AND PERFECT.

Made of porcelain, handsome in appearance. Occupies little more space than the cell it supports. Each cell of battery completely isolated. Leakage is reduced to the minimum by the use of it.

General Superintendent Van Horn, Southern Division W. U. Tel. Co., writes of it:

"We have now in use a thousand or fifteen hundred of your battery insulators, and expect to order many more before the close of the year.

We have never used any battery insulator that equals it in any respect. In fact, it appears to be as near perfect as we can reasonably expect, in a contrivance for that purpose."

Price 40 cents

We offer a very excellent article of Galvanized Wire, superior to any in the market. The linemen on Baltimore and Ohio R. R. say they have never seen its equal for toughness and flexibility.

Special attention given to building.

Estimates given for any amount of material for telegraph construction or extension.

SWITCHES, GALVANOMETERS, RESISTANCE COILS, &c., to order.

Designs for Switch Boards for special service furnished.

SCOTT'S PATENT ANNUNCIATOR,

for Hotels and Residences.

Baltimore, Md.,

MANUFACTURE

Telegraph and Electrical Instruments

OF EVERY DESCRIPTION.

Facilities for supplying any description of Machinery or Material equal to any in the United States.

Patented Dec. 31, 1872.

Over SIX THOUSAND cells of the Baltimore Battery in use by the Gold and Stock Telegraph Company of New York in their Private Line Department, is a sufficient acknowledgement of its merit, as a form of the gravity battery, combining the valuable principles of

Economy, Cleanliness and Constancy,

"—in fact a base-burner."

F. L. POPE
Telegrapher, July 5th, '73.

SELF-FEEDING,

No Sulphate of Copper can reach the Sulphate of Zinc Solution.

The shape of Zinc and Copper, which, with the tube, were patented December 31st, 1872, secures the largest surface with least weight of the metals. Half pound sulphate copper per month, ample supply for No. 2, or 3.

Following is one of the many letters we have from reliable telegraphers:

PIEDMONT, W. Va., September 28th, 1873.

Messrs. WATTS & Co.,
Baltimore, Md.

GENTLEMEN:—On January 1st, 1873, I put up 75 cells of your No. 2, Baltimore Battery, in place of 40 cells of carbon, from which two railroad wires of 100 miles each, are supplied. It has not since been taken down or cleaned, and has required no attention, except to fill the tubes with blue stone, once each month, and replenish the fluid once or twice during this period, made necessary by evaporation.

I am fully convinced, from long experience, that this is superior to any other form of the gravity battery.

It has now been in constant use for nine months, and will not need new zinc until after January next.

Respectfully,
J. G. NESBITT, *Manager.*

ORDERS FOR THIS BATTERY PROMPTLY FILLED.

A large stock constantly on hand.

No. 1 for Electro-motors, R. R. signals or similar service, $2.25
No. 2 ordinary local or Printing Telegraph main $1.75
No. 3 ordinary main $1.25

A very Superior Main Line Sounder.

Brass, $22.50. Nickel-plated, $25.00.

For wrecking purposes or temporary offices, this instrument is without a rival.

A perfect combination, handsome, good-sounding instrument.

NO LOCAL REQUIRED.

Well seasoned black walnut box, large enough for pencils, paper, plyers and office wire, in addition to the instrument, $4.

Larger size for climbers, vises, &c., $5.50.

RELAYS, SOUNDERS AND KEYS,

always on hand, plain or plated.

Our Challange Sounder is the noisest instrument made.

Tillotson's Programme

FOR THE HOLIDAYS.

Attention, Telegraphers!!

☞ In order that we may be able to keep our men employed during the present hard times, we offer the following liberal inducements to purchasers of telegraph material until the

First of January, 1874.

To any person sending us an order for telegraph goods, however small, we will present a copy of Smith's Manual of Telegraphy, gratis.

For an order amounting to from five to ten dollars, we will present one year's subscription to the JOURNAL OF THE TELEGRAPH, or one copy Bond's Hand-book of Telegraph, (British).

For an order amounting to from twenty to thirty dollars, one year's subscription to the Telegrapher, a copy of Pope's Modern Practice of Electric Telegraph, or PRESCOTT'S HISTORY OF THE TELEGRAPH.

For an order amounting to from thirty to fifty dollars, one of either of the following instruments, viz: our Patent Excelsior Instruments for Students' use, our No. 1 or No. 2, Pony Sounder, or our No. 1 or No. 2 Key.

For an order amounting to one hundred dollars, our No. 1, or other style Relay of our manufacture.

For an order amounting to five hundred dollars, our Premium Spring Register.

For an order amounting to one thousand dollars, our Premium Spring Register with No. 1 Relay, Key, Lightning Arrester, and Cut Out, all nickle-plated and combined on marble base.

For an order amounting to ten thousand dollars, our magnificent Set of Sterling Silver Instruments, including Register, Relay and Key, and two Paper Rules, the whole worth $2,000.

Tillotson's Great Specialties.

Johnston's Celebrated Galvanized Line Wire, all sizes, sold at same prices as inferior wire of other manufacture.

The Kenosha Insulators, for which we are the sole Eastern Agents.

The Patent Canvel Screw Glass Insulator.

The New Patent Lockwood Battery.

The Famous Patent Leclanche Battery, for open circuits.

The well-known Patent Hill Battery.

The popular Callaud Battery.

The Patent Nitro-Chromic Battery, for heavy work.

The American Compound Patent Line Wire.

The Bishop Cables, Gutta Percha, Office and Magnet Wires, etc.

The Patent Excelsior Instrument for Amateurs and Students, acknowledged by all to excel any instrument ever designed for this purpose. Its price, its usefulness, its success,—all commend it. It is no toy, but is adapted for circuits of from one to ten miles in length, as well as a mere office circuit.

The Patent Jones Lock Switch.

Rhumkorff Coils and Geissler Tubes, etc.

The Premium Spring Register.

The celebrated Relay Magnets, from their peculiar construction, continue to receive the encomiums from Telegraphers to which they are justly entitled.

Our Sounders, Keys and other Machinery are not excelled.

Carbon, Grove, Smee and other Batteries always in stock.

JOURNAL OF THE TELEGRAPH.

VOL. VI. NO. 26. NEW YORK, DECEMBER 15 1873. WHOLE NO. 147.

MILLIKEN'S REPEATER.

Numerous devices have been from time to time invented and employed for operating, automatically, telegraphic repeaters, combining two or more Morse circuits for the purpose of direct transmission, greater distances than practicable without such combination. That is to say, devices to automatically prevent the breaking of the sending circuit at any point, other than at the key of the sending operator.

In the old "switch repeater" the contact points which would otherwise break the sending circuit, are cut across by the use of a hand switch provided for the purpose, but the necessity of reversing its position whenever a break occurs, or the direction of transmission is to be reversed, renders this method extremely troublesome and uncertain, especially when transmitting through two or more repeaters.

In any arrangement for doing this, or an equivalent service automatically, some device for the purpose must be applied in each instance of opening the circuit and removed upon again closing the same. By this means, the action of the repeater may be reversed at pleasure, for the reason that, whichever of the two closed circuits assumes the initiative by opening, operates the repeater in such a manner as to prevent itself being opened at that point also; while at the same time, or substantially so, a break is transmitted to the next circuit in combination.

Various devices may be successfully applied to accomplish this, provided the lines be so nearly free from escape as to allow the armatures of the relay magnets on each side of the repeater, to work in unison; but it becomes a more difficult matter in working very long circuits, or over escapes necessitating high relative tension of the relay springs.

The chief difficulty, then, encountered by automatic repeaters in general, is that of so arranging as to continue this device in operation for such length of time after the closing of the circuit by the sending operator, as will enable the relay itself to control and close its armature by attraction, thus providing against a false break upon its removal.

In consideration of the conditions under which repeaters are really valuable, this feature is of vital importance.

No false breaks can occur from such cause in the use of the Farmer and Woodman repeater, patented in the year 1857, and from this fact the invention seemed for a time likely to prove a grand success and a final solution of the repeater problem; but experience demonstrated that the means by which the desired object was attained, introduced another feature, rendering the repeater exceedingly difficult to operate and which was fatal to its general adoption.

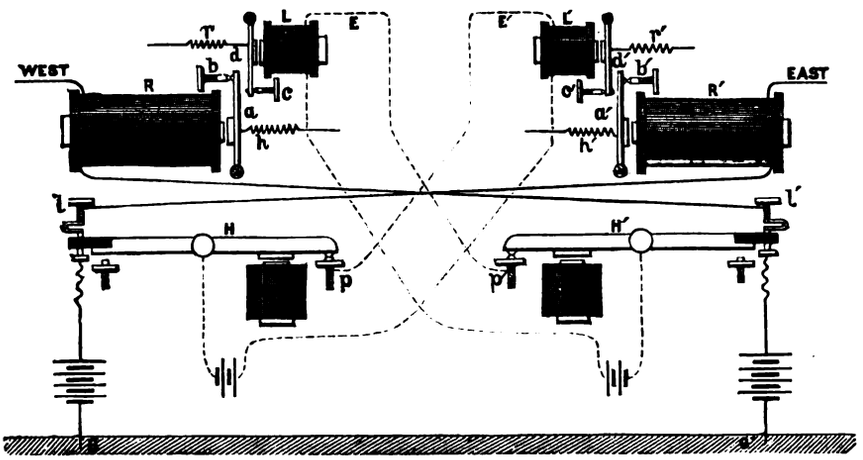

Figure 1.

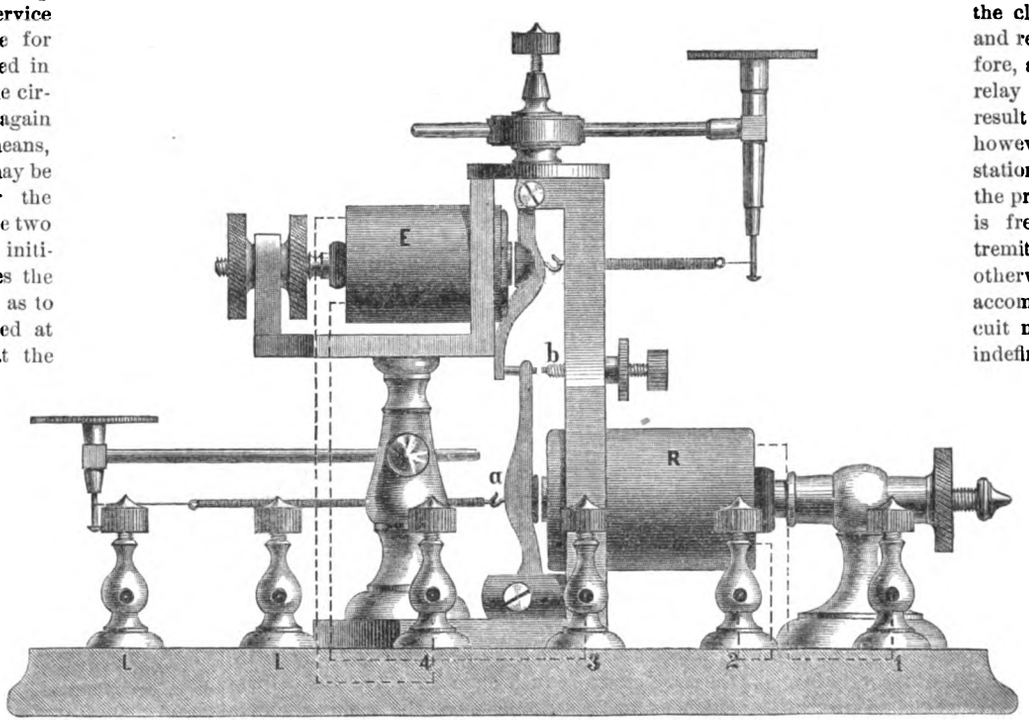

Figure 2 (A) (B).

The device employed by Messrs. Farmer & Woodman, is mechanical in its operation and consists of a light metallic hook, having an arm and so situated that the armature lever of the sounder on the sending side of the repeater, in its upward movement and before breaking the main receiving circuit, strikes this arm, and pushes the hook under the extremity of the opposite sounder armature lever, which is thus prevented from moving a distance sufficient to open the sending circuit at that point; a full play of the armature levers being necessary in order to break the main circuits, by lifting contact springs. This hook and arm would be returned to their original positions by the operation of a spring provided for the purpose, except for the *pressure of the armature lever upon the hook*, causing the detention of the latter until the relay magnet of the receiving circuit becomes sufficiently charged to draw its armature forward, followed, of course, by the closing of the local circuit and release of the hook. Therefore, any desirable tension of the relay spring cannot change the result in this respect. In breaking however, the distant receiving station must open the circuit at the precise instant when the hook is free (or not under the extremity of the sounder lever), otherwise this object cannot be accomplished, although the circuit may be held open for an indefinite time.

Inasmuch as the proportion of time during which the sounder lever and hook are locked, depends upon the relative tension of the relay spring on the receiving side, it follows that oftentimes great skill must be exercised by the distant receiving operator, in order to throw in a break at the right moment.

The custom was, in the use of this repeater, to make a succession of dots, until one of the intervening breaks chanced to make a hit; but the loss of time and uncertainty in this respect, caused the abandonment of the system.

In the Milliken repeater, the defect to which we have referred, as generally found in automatic repeaters, is entirely obviated, without the introduction of any feature detrimental to its operation in other

Digitized by Google

respects (as in the case of the Farmer and Woodman invention) by the employment, in connection with each of the repeater relays, of an extra local magnet, the armature lever of which, when drawn back by its spring against the lever of the relay with which it is placed in mechanical combination, prevents the movement of the latter, when the main circuit through the relay is broken. The adjustment of these extra local magnets and of their armature springs, being entirely independent from that of the relays, it is simply necessary that such springs be *actually and relatively* stronger than those of the relays with which they are mechanically combined.

By this means, false breaks arising from any required tension of the relay spring on the receiving side of the repeater, are effectually prevented; as will be seen by the following description of its construction and operation, reference being had to the accompanying diagrams.

Figure 1 represents the apparatus employed and shows the connections between its parts, with the exception of those of the ordinary local circuits, to which reference is not here necessary, the relay on each side operating its sounder in the usual manner. The course of the extra local circuits are shown by dotted lines. The extra local magnet on each side, is placed in a position opposite to the relay and at a convenient height, so that its armature lever, when drawn back, may press against that of the relay, as shown in the diagram.

R and *R'* represent the relay or receiving magnets, placed in the main circuits, which connect the batteries and earth *G'* and *G* through the repeating points *l'* and *l* of the opposite sounders respectively.

LM and *LM'* are the local sounder magnets, each operated by the relay on the same side.

L and *L'* are extra local magnets operated respectively by the movement of the opposite sounder levers *H'* and *H*, as indicated by the dotted lines *E* and *E'*.

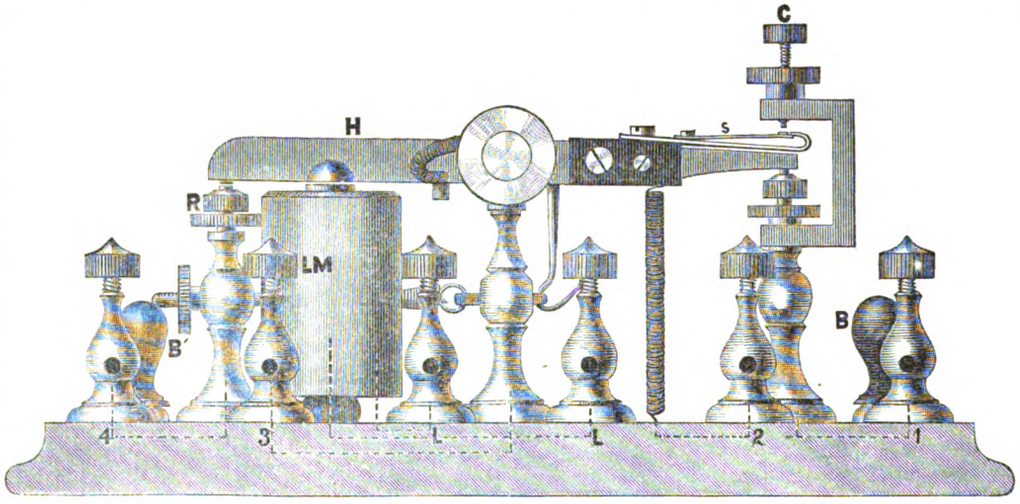

Figure 3 (A) (B).

Now, if the western main circuit be broken at a distant station, the movement of the armature lever *a* of the relay *R*, breaks the local circuit of the sounder *LM* at *b*, causing the sounder lever *H*, to break the extra local circuit *E'* at *p*, thus allowing the armature lever *d'* to be drawn by the spring *r'* against the extremity of the relay armature *a'*. The same movement of the sounder lever *H* also breaks, at substantially the same time, the eastern main circuit at *l*, but the lever *a'* is prevented from being drawn back, and thereby causing a break in the western main circuit *l*, by the tension of the spring *r'*, which is so adjusted as to effect the release of the armature *d'*, from the attraction of the magnet *L'* before the armature *a'* is released from that of the relay magnet *R'*, the spring *r'* being also of sufficient strength to hold the armatures against the stop *b'* in opposition to spring *h'*.

If now the western circuit be again closed, the return of the armature lever *a* by the attraction of the relay magnet *R* closes the local circuit on that side of the repeater, followed by the closing of the eastern main circuit at *l*, and also of the extra local circuit *E'* at *p*. The relay armature lever *a'* being again attracted by the relay magnet *R'*, upon the closing of the eastern circuit, no longer requires to be mechanically held against the stop *b'* by the armature lever *d'* and it is therefore drawn against the stop *c'* by attraction of the extra local magnet *L'* consequent upon the closing of its circuit *E'*, but in thus returning the repeater to its normal position, it must be understood that in case the spring *h'* is of high relative tension, such tension being necessary in order that a break may be received at the relay *R'* from the distant eastern station, a corresponding increased relative tension must be given to the spring *r'*, otherwise the extra local magnet *L'* will become sufficiently charged to overcome the spring *r'* and so draw away the armature lever *d'* before the relay magnet *R'* becomes charged to the extent necessary in order to hold its armature *a'* in place, in which case it will be momentarily released and a false break ensue from a reverse action of the repeater. This forward movement of armature lever *d'* may, however, be retarded to any degree necessary, by a proper tension of the spring *r'*, even though it be held almost constantly against the armature lever *a'* and yet a break from the distant eastern station be promptly effective, provided the relay *R'* be properly adjusted to receive it. For instance, the distant receiving station breaks. We will suppose the western circuit to have been open at that instant, at the key of the sending operator. Instantly upon closing it, the relay *R* closes it local circuit, followed by the closing of the extra local circuit *E'* at *p*. The eastern main circuit, however, being open at the distant office, the armature lever *a'* will be drawn back instantly upon the first forward movement of armature *d'*. Thus the action of the repeater may be reversed, it being understood, of course, that its opposite parts may be operated in precisely the same manner.

It should be remembered, that in closing the main circuits at *l* and *l'* by movement of armature levers *H* and *H'* springs are used for the purpose on account of the additional contacts necessary to be made by the same levers, at their opposite extremities. Inasmuch as by this arrangement the main circuit is closed before that of the extra local, and remains closed an instant longer, it may be regarded as favorable to the action of the repeater, although not essential, its successful operation being entirely due to the principle applied, which is, that *the ratio of the resistance of the extra local armature spring to the attractive force of its magnet, is greater than the ratio of the resistance of the relay armature spring to the attractive force of the relay magnet*, the combination being as shown in the diagram.

It is, therefore, not necessary to allow full play to the sounder levers, for the purpose of gaining time between the closing of the main and extra local circuits. On the contrary they should have the *least possible movement*, with due regard to securing perfect connections at the spring contact points, and to convenience in reading.

Figures 2 (*A*) (*B*), and 3 (*A*) (*B*) will illustrate the connections from helices, contact points and switches, to binding screws arranged upon the base boards, the relay and its sounder of one side of the repeater being designated in the description by the letter (*A*), and those of the other side by the letter (*B*), by which plan the connections of the full repeater may be represented in drawings of one side only.

L and *L*, in figure 2, are binding screws connecting respectively with the stop *b*, and armature lever *a*, forming the contact points of the ordinary local circuit.

L and *L* figure 3, are also local circuit binding screws, connecting with the sounder coils *L M*, these four binding screws being connected together, on the *A* side of the apparatus, with a local battery in the same manner as those of an ordinary relay and sounder.

Duplicate connections are made at and between the other relay and sounder, consequently the relay of figure 2 (*A*), operates the sounder of figure 3 (*A*), and the relay of figure 2 (*B*), that of figure 3 (*B*).

Binding screws 1 and 2, figure 2 (*A*), are the terminals of relay coils *R*, and connect by wire, one with the key, thence to line and the other with the binding screw 1, figure 3 (*B*); thence through the post and contact points formed by the adjustable screw *c* and spring *s*, (the latter being insulated from the sounder lever *H*); thence by the spiral connecting wire, to the binding screw 2, at which point the circuit is completed by connection with battery and earth.

Binding screws 3 and 4, figure 2 (*A*), are the terminals of extra local coils *E*, and connect, one with a battery of one Grove cell, or its equivalent, and the other by a connecting wire, with binding screw 4, figure 3 (*B*); thence through the post and contact points formed by the adjustable screw *R*, and sounder lever *H*; thence by the middle post to binding screw 3, which, being connected to the other pole of the Grove cell, completes the extra local circuit.

The main and extra local circuit connections between the binding screws of figure 2 (*B*), and those of figure 3 (*A*), are made in a similar manner as those described, referring to the same numbers; the internal connections being, of course, the same.

The switches *B* and *B'*, figure 3, are used only for the purpose of connecting across the contact points of the main and extra local circuits, when desirable to use each side of the repeater, as an ordinary relay and sounder. One point of switch *B* therefore connects with binding screw 1, and the other with binding screw 2.

One point of switch *B'* connects with binding screw 3, and the other with 4, this arrangement being the same on each side.

MATHEMATICS FOR NON-MATHEMATICIANS.

By W. PAGET HIGGS, LL.D., D.Sc.

Division I.—The Algebra of Constant Quantities.

Dicision, Fractions and Ratio.

The reader may ask why the common order of mathematical books is departed from, by bringing to one focus the consideration of the principles of so apparently diverse subjects as division, fractions and ratio. Perhaps the most efficient answer will be found in a general statement of the symbols employed in the algebraic representation of these processes.

I. The operation of *dicision* is, algebraically, represented in two ways :—

a. The quantity to be divided (the *dividend*) is written before the sign ÷ (to be read "divided by"), and this sign precedes the dividing quantity (the *divisor*). Thus $a \div b$ is to be understood to indicate the division of a by b.

b. The dividend is written above a short line, the divisor below the line, thus $\frac{a}{b}$.

In both cases the result of division is termed the *quotient*. And the entire operation and result may be stated in the form of an equation, either as—

(*a*). $a \div b = q$; or as—

(*b*). $\frac{a}{b} = q.$

II. The last expression, $\frac{a}{b}$, is the general form by which is represented a *fraction ;* illustrated by supposing a to represent an apple, and b the number of parts into which it is to be divided. If we divide one apple in two parts we have, numerically: $\frac{1}{2}$ or one-half as the result. And generally if we divide n things into p portions, or among p persons, each portion will be, or each person will get, that quantity of the things represented by $\frac{n}{p}$.

III. There are two methods of representing the relation or *ratio* of two quantities :—

(*a.*) The most useful is the form of a fraction, as $\frac{n}{p}$; here the ratio expressed is that of the number of things to the number of persons.

(*b*). The other method of representing the ratio two quantities bear to each other is by placing between them a colon (:),—thus $n : p$ has the same meaning as $\frac{n}{p}$, both expressions indicating the relation of the quantities.

Proportion is the equality of ratios. It is a common error to say that "two numbers bear a certain *proportion ;*" correct mathematical language would dictate that "two numbers bear a certain *ratio.*" Only *two ratios* can be said to be *proportionate.* Thus, if we have to divide a apples amongst b boys, or algebraically $\frac{a}{b}$; and if we have to divide n things amongst p persons, or algebraically $\frac{n}{p}$; then if the two ratios $\frac{a}{b}$ (ratio of the number of apples to the number of boys) and $\frac{n}{p}$ (ratio of number of things to number of persons) be equal, we may place between them the sign of equality (=) and the equation expresses a proportion—

$$\frac{a}{b} = \frac{n}{p}$$

or—

$$a : b = n : p ;$$

or, again, substituting the sign :: for the sign of equality—

$$a : b :: n : p.$$

This we see is a return to an earlier arithmetical stage of a rule of three sum. For suppose 6 apples amongst 3 boys, and 4 things amongst 2 persons, we have—

$$6 : 3 :: 4 : 2.$$

The relation, therefore, of division, fractions and ratio is sufficiently close to call for their undivided consideration. The expression—

$$\frac{a}{b}$$

may, we have seen, mean—

I. The number of times a contains b.

II. A fraction, a being the *numerator* and b the *denominator.*

III. The relation or ratio of a and b.

These three heads really express, under different forms, the same notion—the relation of a to b. In each case we may determine the value of the relation by a process of continued subtraction (as in multiplication we arrived at the product by a process of continued addition). Suppose, as a first example, that a represents 10, and the numerical value of b is 2 ; we shall find the value of the relation of a to b or $\frac{a}{b}$ to be 5 ; for we can subtract 2 from 10 5 times.

10	
2	1st subtraction.
8	
2	2nd "
6	
2	3rd "
4	
2	4th "
2	
2	5th "
0	

Suppose, as a second instance, that a should represent 2, and $b = 10$; then we should know that we have to divide 2 in 10 parts or 1 into five parts, taking one of those parts, or $\frac{1}{5}$th.

Let us now study the effect of different algebraic arrangements of the general expression—

$$\frac{a}{b} = q, \text{ or } \frac{10}{2} = 5.$$

In words, this tells us that the result of dividing the dividend (a) by the divisor (b) is the quotient (q). Again—

$$a = q\,b, \text{ or } 10 = 5 \times 2,$$

or the dividend equals the quotient multiplied by the divisor. And—

$$b = \frac{a}{q}, \text{ or } 2 = \frac{10}{5},$$

or, the divisor equals the dividend divided by the quotient.

Besides these equations, there are others expressing fundamental principles; and the chief of these is—

$$\frac{na}{nb} = \frac{a}{b},$$

or the multiplication of the numerator and denominator of a fraction, or the multiplication of the dividend and divisor, by an equal quantity, does not affect the value of the fraction nor of the quotient. Whence it may be perceived—

That the multiplication of the numerator of a fraction by an integer increases the value of the fraction.

That the multiplication of a dividend by an integral quantity increases the value of the quotient.

That conversely the multiplication of a denominator by an integral quantity decreases the value of a fraction.

That the multiplication of a divisor by an integral quantity decreases the value of the quotient.

If we substitute for the term "integral quantity" or "integer" (Anglicé, *whole* number) a fractional quantity, of course the converse only of each rule will hold good.

Rules for Division.

If we observe the rule (the same as for multiplication) that *division of* LIKE *signs yields a* POSITIVE *quotient, of* UNLIKE *signs a* NEGATIVE *quotient*, we may reduce the numerous rules for division given in many of our text-books to the following :

(1). To divide one *monomial* by another,—suppress the letters that are common to both ; subtract the exponents which affect the same letters ; and divide the co-efficients one by another.

(2). To divide a *polynomial* by a *monomial*,—divide each term of the polynomial by a monomial according to the first rule; connect the results by their proper signs (remembering like produce positive, unlike produce negative, signs).

(3). To divide *two polynomials* one by the other,—arrange them with respect to the same letter ; then divide the first terms one by the other, and thence will result one term of the quotient; multiply the divisor by this, and subtract the product from the dividend: proceed to the end in the same manner.

(4). To divide algebraic fractions,—invert the terms of the divisor, and multiply together the numerators and the denominators.

Examples to these Rules.

(1). $$\frac{12a^3b^2c}{3ab} = \frac{12}{3}a^{3-1}b^{2-1}c = 4a^2bc.$$

(2). $$\frac{6a^2 + 12ab - 9abc}{3a} = \frac{6a^2}{3a} + \frac{12ab}{3a} - \frac{9abc}{3a} = 2a + 4b - 3bc.$$

(3). $$\frac{a^3 - 3a^2b + 3ab^2 - b^3}{a - b}$$

Divisor.	Dividend.	Quotient.
$a - b$	$a^3 - 3a^2b + 3ab^2 - b^3$	$(a^2 - 2ab + b^2$
	$a^3 - a^2b$	
	$-2a^2b + 3ab^2$	
	$-2a^2b + 2ab^2$	
	$ab^2 - b^3$	
	$ab^2 - b^3$	

This year the value of gutta percha imported into Great Britain was £315,454; last year, in nine months, £296,331.

ELECTRICITY AND THE SPECTRUM ANALYSIS.

Among many practical applications of spectrum analysis, one of the most important is in the manufacture of steel by the Bessemer process. A blast of air is forced through the melted iron to deprive it of a certain proportion of carbon. If this blast is continued a few minutes too long, or stopped a few minutes too soon, the whole operation is vitiated. By examining the flame of the converter with the spectroscope, the proper time to stop the blast is clearly indicated by the disappearance of the carbon lines and the change to a continuous spectrum.

But the uses of the spectroscope do not stop here. Scientific men have of late been turning their attention in a new direction, that of quantitative analysis by means of the spectrum. Not content with discovering what substances are contained in a given compound, they are devising means to determine the quantity of these substances.

The most recent and perhaps the most important method yet discovered is due to Lockyer of England. It is based upon the following principles: When an alloy is introduced into the electric arch, the most volatile metal will be carried across to the other pole first, and its vapor will form so good a conductor that but little of the less volatile metal will get into the arch. To make the principle perfectly plain, we will quote an explanation given by Tyndall. When showing his audience the characteristic lines of silver and thallium, he found that the latter were far brighter, and that the former were diminished, when a bit of thallium was put in with the silver in the electric arch. "It is the resistance," he went on to say, "offered to the passage of the electric current from carbon to carbon that calls forth the power of the current to produce heat. If the resistance were materially lessened, the heat would be materially lessened; and if all resistance were abolished, there would be no heat at all. Now thallium is a much more fusible and vaporizable metal than silver; and its vapor facilitates the passage of the current to such a degree as to render it almost incompetent to vaporize silver." The more, therefore, of the more volatile metal is present in an alloy, the less of the other can be vaporized by the arch.

Now on examining the arch by means of the spectroscope, Lockyer found lines extending across the whole width of the spectrum and shorter ones reaching only part of the way. The former corresponded to the more volatile, and the latter to the less volatile, metal. Now, as the length of the latter increases with the quantity of the metal present, it is evident that by measuring them we can ascertain that quantity. In these determinations, the electric current is obtained either from a powerful battery, a Ruhmkorff coil or a magneto-electric machine; and the heat of the spark is intensified and at the same time rendered constant by means of Leyden jars of constant surface. Instead of placing the alloy to be tested in one of the carbon electrodes, we might have the electrodes themselves composed of the metals. Suppose we make one of pure gold and the other of some alloy whose percentage of gold we wish to ascertain. Then by separating the electrodes sufficiently, we finally arrive at a point where the gold lines from the alloy no longer meet the lines from the pure gold, but will extend only part of the way, leaving a gap on their half of the spectrum. If we now keep the same distance between the electrodes, and experiment on alloys containing different percentages of gold, the length of their gold lines will be found to vary with that percentage. The length of the lines can easily be measured by causing the reflection of a graduated scale to fall upon the spectrum. In assaying, where we frequently have to do with samples of gold whose fineness differs but little, a series of electrodes of known composition may be prepared; and by comparing them with alloys of unknown fineness, it is easy to tell, by simple inspection of the spectrum, which is the finer. The lines of the one containing less gold will not extend all the way across.

HOW TELEGRAPHING IS DONE IN BRITAIN.

When Mr. Bright addresses his Birmingham constituents, his utterances are not for Birmingham alone, but for the whole country. His long-enforced absence from public duties, and his return to office as a Cabinet Minister, in the present unsettled state of politics, give to his present address far greater importance than has attached to any of his previous speeches. Every daily paper of any importance in every large town throughout England, Ireland and Scotland, had arranged to supply its readers with a verbatim report of Mr. Bright's speech. The *Times* sent its own reporter, and the Manchester and Leeds papers, with the *Glasgow Herald*, sent a combined staff to work in concert. As a matter of course, every word of the speech had to be telegraphed, and to meet the enormous pressure caused by having to transmit five or six independent reports, and to despatch these reports promptly throughout the length and breadth of the land, very complete and very elaborate special provision had been made at the Central Telegraph offices in Cannon street. For heavy work like this, the ordinary Morse instrument would not be nearly rapid enough, and so the mechanical power was augmented by 12 of Wheatstone's automatic instruments, the most expeditious and most perfect telegraphic instrument yet designed—indeed, so complete, that it seems almost that perfection has been attained. The action of the Wheatstone may be briefly explained. The manuscript to be transmitted is placed before a clerk, who presides at the perforating machine. Working as rapidly as the eye can follow, this dexterous operator reproduces the message in telegraph phonography, which is merely a series of dots and spaces upon an endless coil of tape paper, which is paid out from the box before him. As the tape leaves his hands, it exactly resembles the needlework which ladies call "insertion." A skilled operator can "punch" about 2,000 words an hour, equal to a column of ordinary newspaper type. Three dozen perforating instruments were brought down for last night's work, of which six were capable of producing three copies of the same message at one operation. The advantage of this is obvious, as three circuits may be kept going at the same time. The present was the first occasion that these triple perforating machines have been used out of London. From the perforator the prepared tape is taken to the Wheatstone instruments, the end is inserted, a handle is turned, something like the winding up of a musical-box, and the tape slowly passes beneath the "clicking" apparatus, by which the telegraph symbols are reproduced and written down by the receiving machine at the other end, be it London, Liverpool, Manchester, or to whatever town the communication is made. The extended report was last night transmitted by the twelve Wheatstone instruments, which were put in connection with the following circuits: Two to London, two to Liverpool, one to Sheffield, Leeds, Bradford and Hull; one to Bristol, Exeter and Plymouth; one to Darlington, Newcastle, Edinburgh and Dundee; one to Liverpool and Glasgow, one to Glasgow (special), one to Newcastle and Edinburgh; one to Manchester and Leeds (special); and one to Dublin and Belfast. To all these towns the message was sent direct—that is, it was not taken off for retransmission, making a sort of halfway halt, as is the ordinary custom with long-distance telegrams. The only towns that were not in direct communication with Birmingham, and to which the speech was sent either in full or in an abridged form, were Aberdeen, Inverness, Cork, Brighton, Norwich and Ipswich. Altogether, sixty clerks were engaged in the transmission of the reports of last night's meeting. The number of words transmitted was over 120,000, or equal to about sixty columns of newspaper type.—*Birmingham Post.*

NOTE.—We give the above excellent performance due publicity and credit. The time occupied is not given Sixty persons were employed in the sending office and 48 machines. We have only to say that 12 fair American operators with simple Morse keys beneath their fingers could have performed the same work in five and easily in six hours.

The Scientific American publishes an illustration of a postal telegraph carriage, now in use in Great Britain, for opening temporary communications. The idea is to have a movable office, carrying its own cable, apparatus and batteries, which can be transported from place to place, either by road or rail, at the shortest notice, and which can be taken to the wires when the wires cannot be taken to it. This, which is the only carriage of the kind in use for similar purposes, is constructed to carry one of each of the different forms of instrument (six in all) in use in the postal system, and can comfortably accommodate as many as eight clerks in full work. It carries, also, nearly 150 battery cells, and so skillfully is the accommodation designed that these are all stowed away out of sight in odd corners, so that not a single atom of space is lost. Half a mile of three-wire iron-sheathed cable is stowed away as snugly as possible in the "boot," and can be paid out and drawn in with the greatest ease in the world. The telegraph carriage has been used at agricultural shows and races, and similar occurrences, which sometimes take place away from cities.

LUDLOWVILLE, N. Y., Nov. 7, 1873.—In an article in the JOURNAL for Nov. 1st, entitled "Non-resistance of the Earth as a Conductor," is the statement: "The same battery will work to a far greater distance with a circuit half wire and half earth, than when altogether wire." Now, in a short line, of perhaps a quarter of a mile, three cups of Daniell's battery failed to work the circuit (including two ordinary pony sounders), when it was half earth, but worked with the return wire. A similar case was noticed in your columns, followed with your advice to deepen the ground connections and enlarge the plate. This was noticed and followed by us, but with no successful result. Now, what is the trouble? We have a good line, good insulation, good battery, and return wire. The line works O. K. We make earth connections, increase the battery (ground wires in constantly moist earth), and can't get a tick! We have tried everything suggested by theory and experience; still no current. What's the trouble? Please explain, and oblige

J. J. MITCHELL, *Manager.*

Answer.—There are conditions to every statement. The one given had reference to a long circuit. Your battery was small. There may have been obstructions on the face of your ground plate. The strata of soil may have been peculiar. On a short circuit the general statement may prove incorrect. Suppose you double your battery and compare results again.

GREETING TO ARIZONA—THE TELEGRAPH THROUGH TO PRESCOTT.

On Thursday, August 28th, at nine o'clock A. M., work was commenced at San Diego on the San Diego and Arizona Military Telegraph. Yesterday, (November 18th) at one o'clock P. M., the line was completed through to Prescott, Arizona Territory. In one hundred and sixty-seven working days the "boys in blue" have built four hundred and seventeen miles of telegraph. When we consider the fact that the greater part of this line has been constructed through a wild and rugged country, sparcely inhabited, where the settlements are indeed "few and far between" and the facilities for the distribution of material are exceedingly limited, it may be justly claimed that this early consummation of the connection between Prescott and San Diego is wholly unprecedented in the history of telegraph construction. The announcement of the completion of the main line was a thorough surprise, the work having been closed fully a month earlier than the date fixed at the beginning of the operations at San Diego. It is an achievement of which all concerned may well feel proud.

HISTORY OF THE PROJECT.

The history of the project which has just been consummated may be briefly summarized. The necessity of the line was first strongly urged by General Crook and the military officers in the Department of Arizona and was pressed by Gen. Schofield, Gen. Sherman and Secretary of War Belknap. Delegate McCormick, with accustomed zeal and energy took the matter in hand in Congress and ably advocated the appropriation for the prosecution of the work on the floor of the House. On the 21st of February last, the sundry civil appropriation bill being before the House, the following paragraph, as amended by Delegate McCormick, was read:

"For the construction of a military telegraph from San Diego, California, via Fort Yuma and Maricopa Wells, to Prescott and Tucson, Arizona, $50,311,-80."

In a forcible speech in support of this appropriation, Mr. McCormick said.:

* * * "The enterprise properly belongs to the Government, and is in the direct interest of economy and efficiency. I undertake to say that instant communication between the officers of the army in Arizona and headquarters at San Francisco and in Washington would have prevented many of the differences between the citizens and the officers, many of the unsuccessful movements of the troops, a frequent waste of money, and much of the misrepresentation regarding military, civil and Indian affairs in Arizona which has puzzled the Eastern press and confused Congress, the Departments, and the public for some years past. * * * * * * * * * *

Upon every account in the Department of Arizona, where the Government is spending in military operations alone several millions per year, where there are no railroads, where is the largest number of absolutely hostile Indians, and where there must inevitably be active campaigning for some time to come, and after it extensive dealings with the Indians, all the facilities of the telegraph should be promptly provided; and this, in my judgment, and that of all interested, can in no way be so cheaply done as by the appropriation now asked and recommended by the committee."

The appropriation was thereupon agreed to and became a law.

THE WORK OF CONSTRUCTION.

The construction of the line was entrusted to the military authorities, and General Schofield, commanding the Division of the Pacific, at once ordered estimates to be made with a view to the commencement of the work. The direction of operations was confided to General George Cook, commanding the Department of Arizona. Mr. R. R. Haines, District Superintendent of the Western Union Telegraph Company, who has had great experience in telegraph building, was engaged by the military authorities to superintend the construction of the line. The wire, insulators, battery material and instruments were supplied by the Electrical Construction and Maintenance Company, of San Francisco.

The General Superintendence of construction and location of route was under R. R. Haines, of the Western Union Telegraph Company, assisted by Capt. Geo. F. Price, of the Fifth Cavalry. Foremen of Construction, D. McKillop, Geo H. Wilson and A. W. Ladd; Electricians, R. H. Howe, Thos. E. Atkinson and W. B. Ellison; Commanders of troops, Capt. Wm. E. Dove, Capt. Geo. F. Price and Lieut. Jno. F. Trout.

CHINESE TELEGRAPHS.

M. Viguier, of Shanghai, has imagined, says *Galignani*, a very simple system for the transmission, by telegraph, of Chinese messages, and the plan is at this moment adopted at Shanghai and Hong-Kong by the Great Northern Telegraph Company. The Chinese writing cannot be reproduced by the ordinary telegraph apparatus; consequently, to permit the Celestials to send telegrams in their own language, M. Viguier has devised the following expedient: Of the 41,000 characters which compose Chinese writing, 7,000 only are employed ordinarily, and are indispensable for every-day requirements. It being established that every educated Chinese ought to know at a glance to which of the 214 radicals each character relates, M. Viguier has ranged in columns these 7,000 characters under their respective radicals, and affixed to each a number from one to 1,000. Thus disposed, the characters are printed on seven large sheets, which the Chinese have to procure, and by means of which they can, in a very short time, find the signs they want. They write figures instead of letters, and in using certain conventional signs for the address and signature, the message may be transmitted as easily as any other. The receiving-office is provided with a table bearing the same series of numbers from one to 1,000, and the corresponding characters. There is no doubt that the application of M. Viguier's system will give a great impulse to the use of the telegraph among the Chinese, and contribute powerfully to spread that mode of correspondence over the whole Empire.

ON THE SOURCE OF ATMOSPHERIC ELECTRICITY.

In a recent number of the Journal of the Austrian Meteorological Society, Mühry has contributed somewhat to a better understanding of the obscure subject of atmospheric electricity, by considering it in reference to its geographical distribution. He maintains that the distribution over the earth's surface of the quantity of electricity is in general parallel with the distribution of temperature; it increases and diminishes with the latter, as well in reference to the earth's surface as in reference to the time of the year and the day. The insolation of the earth is to be considered as the source of the atmospheric electricity: its origin lies in the insulating stratum, and it is in this respect to be considered as terrestrial and not celestial. Atmospheric electricity diminishes as we go from the equator to either pole, and it therefore does not depend on precipitation of vapor, but on temperature. Terrestrial magnetism increases in force as we approach the poles. Electricity is strongest in dry, hot deserts. Contrary to the theories of Dellmann and of Peltier, Mühry holds that aqueous vapor is merely the conductor, or rather convector, bearing the electricity into higher regions. He suggests that it is more important to meteorology to observe the quantity than the kind of electricity, and that the simple straw electrometer of Volta will suffice, instead of the more delicate and complicated instruments that have been deemed necessary. The most important problems that are now remaining to be solved are, he thinks, the details of the geographical distribution in reference to latitude, longitude, and dry and moist climates.—*Harper's Monthly.*

A NOVEL AND SIMPLE ELECTRIC LIGHT.

Dr. Geissler, of Bonn, Germany, whose name is inseparably associated with some of the most beautiful experiments that can be performed by the agency of electricity, makes an electrical vacuum tube that may be lighted without either induction coil or frictional machine. It consists of a tube an inch or so in diameter, filled with air as dry as can be obtained, and hermetically sealed after the introduction of a smaller exhausted tube. If this outward tube be rubbed with a piece of flannel or any of the furs generally used in exciting the electrophorus, the inner tube will be illumined with flashes of mellow light. The light is faint at first, but gradually becomes brighter and softer. It is momentary in duration; but if the tube be rapidly frictioned, an optical delusion will render it continuous. If the operator have at his disposal a piece of vulcanite, previously excited, he may, after educing signs of electrical excitement within the tube, dispense with his flannel or fur. This will be found to minister very much to his personal ease and comfort. He may continue the experiment and with enhanced effect, by moving the sheet of vulcanite rapidly up and down at a slight distance from the tube. This beautiful phenomenon is an effect of induction.—*Scientific American.*

West India and Panama Telegraph.—The report shows that the receipts for the year amounted to £26,185, and the expenses, including interest, to £25,669, leaving a balance of £485. The unsatisfactory result of the twelve months' work is ascribed to the various interruptions in the company's cables, which are intimated to be due to their imperfect manufacture and laying. The suit between this company and the India-rubber Company is expected to result beneficially to the former. The subsidies received during the year have been only £5,401 out of the full sum of £16,800, some of the governments having withheld their payments during the interruptions.

The Brazilian Submarine Telegraph Company have notified that, owing to the tempestuous weather, which has prevented the opening of the first section of their cable between Lisbon and Madeira, they have agreed to a proposal of the contractors to defer sending the second section to sea until the Spring of 1874, and that the arrangement will enable the Board to postpone the payment of the final call until the 31st of March, 1874. It is anticipated that both the second and third sections will leave in April, when the repair of the first section will also be proceeded with, in order that the whole line may be in working order by the Summer of next year.

NOTES AND QUERIES.

AUGUSTA, Arkansas.—Will you please advise me of the practicability of Watts & Co.'s Main Line Sounder; would you recommend it for general use on a circuit from one to two hundred miles? Whose box relay is best adapted for general use? An answer through JOURNAL or otherwise will greatly oblige.

Ans.—We can only answer that every man who advertises sounders in the JOURNAL makes them better than anybody else, so far as we know. Watts & Co.s' must be good, they advertise so well.

Please inform me through your paper why the cups of an Electropoion Battery foam over, and oblige the "STATE OF NEVADA."

Ans.—Just as men do when they fight. The foam is caused by the elements attacking each other.

A., who resides at "R.S," telegraphs B., at "S.C," asking B. where he can reach C. with telegram. B. refuses to reply to A., saying he does not want A. to know where C. is. Operator at "S.C" knows that C. is in the city, and could give A. the desired information. Would it be consistent for him to do so?

"PLUG."

Answer.—Certainly not.

A READER.—If consistent, please give, through your valuable paper, a brief description of the printing instrument known as "Gray's Patent." Also, Sholes & Glidden's type printer, and the method of constructing a "condenser" with an approximate formula of the inductive effect a given number of plates, of a given size, with given amount of battery, and oblige.

Answer.—We will do so whenever we have the data desired.

L. D.—Where can "Geo. D. Teller's American Telegraph, Post-office and Express Guide" be had, and what is the price of it?

How should a "pre-paid answer" be checked?

Ans.—Teller's Guide is published in Buffalo, N. Y. Price $8. Check a prepaid answer "collect."

Can the JOURNALS, to complete the files of this office from the beginning, be supplied, it only having the numbers from June 15, 1872?

Will provision be made for names of new offices when the space left for that purpose in the Tariff Book is full, or will each office make such arrangements to suit themselves? I notice that the blank space of two States is already filled. Please answer in next JOURNAL.—Very respectfully, R. Ck.

Ans.—We are unable to supply full files, some numbers being out of print. We are informed by the Tariff Bureau Department that offices are expected to insert a blank leaf for additional names until a new book is furnished, and which will not be long delayed.

To the Editor of the Journal of the Telegraph:

Some of the debaters on the proposed change of alphabet seem to think if the *spaced* letters were done away with, there would be no bulled messages. Perhaps not. A message was sent to a repeating office, addressed to "Dr. H. G. Westlake, Hillsdale, N. Y." Operator (?) gave O. K., and forwarded it to Dr. H. G. West, Lakeville, Ct. Another, sent same operator, read "Wright is nominated. Be here Tuesday, and I will explain." He sent it along: "Wright is comforted. Will be here Tuesday, and will explain." How is that?

That is a severe specimen.—ED.

ATMOSPHERIC ELECTRICITY AND OZONE

Was the title of a paper read by Dr. George M. Beard of New York, before the Sanitary Science Association. He said that it has been shown that there are two daily tides of positive atmospheric electricity. In the morning between 6 and 9 o'clock, the atmospheric tide is at its height, falling somewhat between 2 and 5 P. M., rising again between 6 and 9 P. M., and falling to a minimum between 2 and 5 A. M. Similar variations are noticeable in the months, the tide of atmospheric electricity being highest through the months of January and February, gradually subsiding in the months of March, April, May, June, July, and August, when it is at its minimum, and gradually rising again through September, October, November, and December. It has been stated that there is a relation between ozone and intermittent and remittent fevers; that rheumatism is prevalent when ozone is deficient; and that when ozone is in excess, diphtheria, scarlet fever, small pox, measles, scarlatina, and other cutaneous affections become prevalent.

Comparative researches regarding atmospheric electricity, if conducted to a large extent under government supervision, would help to explan the extraordinary stimulative character of the climate of California, to explain the fact that sunstrokes are almost unknown on the Pacific coast, and perhaps elucidate some of the unkown causes of other wonderous effects of our climate.

THE OPEIOSCOPE.

This is a new and simple instrument, suggested by Professor A. E. Dolbear, for the purpose of demonstrating the pulsations of sound. Take a tube of any material, from one to two inches in diameter, and anywhere from two inches to a foot or more in length. Over one end paste a piece of tissue paper or a thin piece of rubber or goldbeater's skin; either will do. In the centre of the membrane, with a drop of mucilage, fasten a bit of looking glass not more than an eighth of an inch square, with the reflecting side outward, of course. When dry, take it to the sunshine, and, with the open end of the tube at the mouth, hold the other end so that the beam of reflected light will fall on the white wall or a sheet of paper held in the hand. Now speak, or sing, or toot in it. The regular movement of the beam of light with the persistance of vision presents very beautiful and regular patterns, that differ for each different pitch and intensity, but are quite uniform for given conditions. If a tune like "Auld Lang Syne" is tooted slowly in it, care being taken to give the sounds the same intensity, a series of curves will appear, one for each sound and alike for a given sound, whether reached by ascension or descension, so that it would be possible to indicate the tune by the curves; in other words, it is true phonautograph.

THE recent establishment of a signal station at Havana, Cuba, brings to notice a number of meteorological observations that have been made at the Jesuit College in that city during the past twenty-five years. The regular publication of these observations and the deductions that may be drawn from them lead to the conclusion that science will receive very valuable aid from this station in the West Indies. The prevailing wind in this region never deviates more than a few degrees from the east. The total number of rainy days in the year is, on the average, one hundred. Numerous coincidences have been observed between magnetic disturbances and local storms or hurricanes, also between the former and auroras, visible perhaps in distant lands. On the other hand, very frequently the records at Havana show remarkable magnetic purturbations that have not been recorded by the photographic apparatus at Greenwich, England. The amplitude of the daily barometric range is least in June and July, and greatest in the winter months. Fourteen years of observations have been insufficent to determine any certain law respecting the years of hurricanes. They are, however, as is well known, far more frequent from July to January than during the other half of the year. A careful investigation of the terrible hurricanes of October, 1870, leads the Rev. R. P. B. Vines to the conclusion that the winds circulating around the centre of the cyclone describes a circle, and the whole cyclone describes a curve on the earth's surface, such as would be given by wrapping a spiral around a parabola, the folds of the spiral being closest at the apex of the curve. The rate at which the vortex of the cyclone of the 7th of October crossed the island of Cuba was only four miles an hour. The second storm, of the 19th of October, began moving at the rate of nine and a half miles, and increased to twenty miles an hour. The discharges of electric fluid were very intense, and at Cardenas an appearance similar to the aurora borealis were visible for ten minutes. The magnetic needles were very much disturbed. The rising of the sea under the centre of the cyclone is attributed by Vines to the low barometer prevailing there, to which also he attributes certain slight shocks of earthquake, due to the violent expansion of gases confined within the cavities that abound in the island.

THE American man of leisure is a sort of lost dog. The people are so busy, they have so long associated personal importance with action and usefulness, that it is all a man's life is worth to drop out of *active* employment. If a Vanderbilt should quietly release his hold of the vast railroad interests now in his hands, and should never more show his face in Wall street, he would practically shrink to a nonentity. If a Stewart should retire to enjoy his piled-up millions in the quiet repose of his palace, he would cease to be an object of interest to anybody. It is undeniably true that there is nobody in America who has so hard a time as the man of leisure. The man who has nothing to do, and nobody to help him do nothing, may properly be counted among the unfortunate classes, without regard to the amount of wealth he possesses. This is, doubtless, the reason why so many who retire from a life of profitable labor come back, after a few months or years, to their old haunts and old pursuits. They see that the moment they count themselves out of active life, they are counted by their old acquaintances out of the world. They become mere loafers and hangers-on; and a certain sense of vagabondage depresses them. The climate is stimulating, time hangs heavy on their hands, business is exciting, business associations are congenial and attractive; and so they go back to their industries, never to leave them again till sickness or death or old age removes them from the theatre of their efforts.—*Scribner.*

INFORMATION is wanted of Hiram McGonegal. Address U. S. McGonegal, Oak Orchard, Ottawa Co., Ohio.

THE friends of M. D. Buckwell desire to hear from him. VAN WEST, O.

HONOR TO WHOM HONOR IS DUE.

MEMPHIS, TENN., Nov. 24TH, 1873.

I see no mention has been made in the JOURNAL of the fact that the managers and employés of the Memphis office, during the prevalence of the late yellow fever epidemic, when more than a thousand were sick, and hundreds dying daily around them, and when every citizen had left the city that could leave, remained bravely at their post. The names of these brave men should be published and their worth acknowledged. Their names are as follows:

G. M. Baker, Manager.
D. O. Dyer, Chief Operator.
Howell Sigler, Assistant Chief Operator.
I. J. Fowler, Operator.
Chris. Reilly, Operator.
Marco Paoli, Operator.
Peter Fowler, Operator.
Charles H. Patch, Operator.
* Cornelius McCarthy, Operator.
E. W. Gibson, Operator.
* J. N. Rust, Operator.
G. A. Putnam, Operator.
W. H. Joyce, Book-keeper.
C. H. Howe, Assistant Book-keeper.
E. A. Gaston, Clerk.
Charles Marable, Clerk.
W. W. Brown, Office Boy.
J. M. Mullins, Office Boy.
William Clements, Battery-man.

* Mr. McCarthy died with and Mr. Rust had the fever.

WELLINGTON.

AN ECONOMICAL COPYING PRESS.

CHICAGO, Nov. 27, 1873.

I will endeavor to redeem the promise made to you recently, that I would give you in writing a few points in regard to copying messages. Several times when traveling I have asked operators at railroad stations if they retain copies of Western Union messages. They have always answered that they do; but as they are not provided with letter presses, have to write out copies. I will suggest for the benefit of the telegraphic fraternity a simple method by which messages can be copied more easily and rapidly without a screw press than with one.

Two years ago I saw the manager of a St. Louis office copying messages with a large wooden rolling pin more rapidly and easily than it could be done with a press. I presume the same rolling pin has been in use ever since The process consists in making the pile of messages with dampened sheets between, the same as for the press, and then rolling the pin over them once or twice with a moderate pressure.

In Chicago office an iron roller hung in a bale with a handle has been in use a long time. The weight of this iron roller is sufficient without any other pressure. When not in use it is rolled into a trough or groove at the back edge of the table, where it is out of the way.

The wooden rollers can be supplied to railroad stations or small offices on requisitions from District Superintendents. I am having some iron rollers made for use in the larger commercial offices in Central Division. Letters can be copied in a book with one of these iron rollers as well as with a screw press.

I have seen clothes wringers used in some offices for copying messages; but in my opinion the rolling pin does the best work and the most easily.

Another feature of this method that ought to recommend it at the present time is its cheapness. Screw presses are expensive and are quite apt to get broken.

Very truly yours,

THOMAS ORTON.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is over 8,000. It goes to every State, Territory and Province on the Continent. It has become a necessity, and is always welcomed as a friend. No better medium for advertising exists.

TERMS:

TWO DOLLARS PER ANNUM IN ADVANCE.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, DECEMBER 15, 1873.

MANY subscriptions to the JOURNAL expire with the close of the volume. As the paper is invariably stopped at the expiration of the term it will be well for those who desire to keep posted in current telegraphic information to renew at once.

WE are tempted to give notice that no communications will hereafter receive attention which are not written with such care as to enable us to hand them to the printer without labor of our own. Some really valuable papers come to us so shabbily, that they merit no courtesy at our hands. If it is worth writing to us at all, it is worth a little care in making your paper intelligible and fit for use.

THE HUBBARD JOB ONCE MORE.—Mr. Ramsey has introduced a bill in the Senate to provide for transmission of correspondence by telegraph. In all substantial particulars it is identical with the so-called "Hubbard bill," for connecting the telegraph with the postal service, which has been introduced in preceding Congresses and fully published. Its main feature is an authorization for the Postmaster-General to contract with the proposed Hubbard Postal Telegraph Company for transmitting correspondence by telegraph as his agent.

WE have received from Washington a lengthy and excited detail of a fraud said to have been practiced on an operator in the Department of the Interior of that city. It would make good reading, no doubt, but we cannot publish it. The manager who will take a message from a "Notorious Hotel and Telegraph Beat," and send it before payment is made, deserves to suffer loss. Nor can we see that we are called upon to publish the name of the cheater to assuage the feelings of the cheatee. A communication showing that a telegraph manager accepted a message at Washington, D. C., to be delivered in Brownsville, Texas, in 15 minutes, would only prove that there was a very soft man somewhere at the National Capitol, and who would be damaged much more than the author of his wrongs. We hope his loss of $5.73 will leave him a wiser and a better man.

WORK WELL DONE.

As we write these closing words of the year, we are glad to be able to associate therewith an admirable piece of telegraphic work. Success is always pleasant. In the case before us, it is especially so, because the success reveals the means by which it was accomplished.

The transmission of the President's Message, by telegraph, throughout the country, has come to be regarded as a test, not only of the capacity and mechanism of the lines employed, but of the direction and manipulation. Failure in either would, of necessity, neutralize and obscure the others. Skill in the arrangement of the details and force employed, intelligent precision and conscientiousness in labor, and perfect mechanical conditions, are all needed to make each available. When, therefore, these are found in combination, a system more or less perfect may be presumed. The transmission of the recent message of President Grant, we think, illustrates such a condition of telegraphic service, and on which the country may properly congratulate itself. It gives evidence that, year by year, communication by telegraph is assuming easier and more harmonious conditions. And the advantage of these special performances is, that they reveal the employment of positive administrative talent in the current execution of telegraphic work. We cannot illustrate this better than by giving our readers the following reports.

FROM MANAGER A. S. BROWN.

NEW YORK, Dec. 3d, 1873.

GEN. T. T. ECKERT, Genl. Supt.:

As a record which may be useful for future reference, I respectfully present the following report of a part of yesterday's press work. The President's Message, containing 10,635 words, was received here, from Washington, on eight wires, with drops at Baltimore and Philadelphia. Its reception commenced at 1:13 P.M., New York time, and was completed in an average of fifty-nine minutes.

Six manifold copies were taken, four of which were delivered to the Associated Press, and the other two used for sending from New York to the Western and Eastern Press.

Accompanying the Message were the text of the Spanish Protocol (490 words) and a synopsis of the report of the Secretary of the Treasury (515 words.)

The President's Message, Protocol and synopsis, were sent to Boston on four wires, dropping copies at New Haven, Hartford, Springfield, Worcester, and Providence. On these circuits, the report was finished at 3:40 P.M.

To the Western press, the reports were sent on four wires, finishing at 3:25 P. M.

Notwithstanding the very unfavorable weather—a thick, drizzling rain prevailing at the time, and for the previous twenty-four hours—the entire report was received here and forwarded East and West, in better time, and, I think it safe to say, in better shape, than ever before.

Very respectfully,
A. S. BROWN.

FROM SUPERINTENDENT BATES, PHILADELPHIA.

THOMAS T. ECKERT, Genl. Supt.:

The President's Message was handed to us, in Washington, at 1 P.M., and was sent to Baltimore, Philadelphia, and New York, on eight wires. The first closed in forty-two minutes; the last, in eighty minutes. There was some interruption, caused by sleet; otherwise, the transmission would have been completed in three-fourths of the time employed. Regular business suffered no delay. The Message was sent to Pittsburgh for the Western Press, in three hours, by four wires, the sleet preventing greater speed. To Pottsville, Pa., it was sent in two-and-a-half hours, against four-and-a-half hours taken by the Automatic Company.

D. H. BATES, Supt.

Commenting on this excellent performance, the *New York Tribune* says: "Credit is due the officers and operatives of the Western Union Company for the excellent arrangements made and the manner in which they were carried out. The connection of the different portions of the matter was perfect, and not a break or omission occurred from beginning to end. The entire report—12,325 words—passed through the Associated Press office in one hour and twenty minutes, and was all in the offices of the evening papers at 2:30 P.M."

It may be said that the speed of transmission was not extraordinary. The average was 1,540 words per hour. 2,500 words have been transmitted in a similar period, in certain test cases. But when the exceeding accuracy of the work is considered, and the fact that six copies were manifolded by each receiver, we regard Mr. Brown quite justified in claiming for the execution unusual excellence and success.

In the inaugural address before the French Association for the Advancement of Science, the President, M. de Quatrefages, said: "The devotees of literature accuse science of stifling sentiment and imagination. What!" answers the President, "science stifle sentiment, imagination, she who brings us every hour into the presence of wonders! She lower intelligence who touches on all the infinities! When *litérateurs* and poets know science better, they will come and draw from her living fountain; like Byron of our time, like Homer of yore, they will borrow from her striking imagery, descriptions whose grandeur will be doubled by their truth. No, the study of science will never suppress the genius of an inspired poet, of a true painter, of a great sculptor. But she will bring more light to the path of an erring soul. She will, perhaps, transform into a wise man, or, at least, into a citizen, useful to himself and others, one who, without her, would only have been one of those pretended incomprehensible geniuses, destined to perish of misery, of impotency, and of pride."

THE testimony of twenty years' experience in deep sea cables goes to show that the insulating substance suffers nothing from continued submersion in sea water. On the other hand, it is known that the great pressure to which a deep sea cable is subjected tends to increase the density and, consequently, the efficiency of the insulator.

ANOTHER ARGUMENT IN FAVOR OF POSTAL TELEGRAPH.—On the night of November 18, Exeter Hall was filled with the employés of the London Post-office, who had met to enforce their claims to higher pay. A member of Parliament was in the chair, and a number of prominent politicians were on the platform. The "sense of the meeting" was that the pay received by the men was not sufficient to keep them from starving.

CLOSE OF VOLUME VI.

With this issue the Sixth Volume of the JOURNAL OF THE TELEGRAPH is brought to a close, and when we say that the closing volume is the best of the series we are confident that our assertion will be fully confirmed by the judgment of our readers. The JOURNAL has not been given to trumpeting its own praise—it has not been necessary ; its contents, and the care and expense which have been bestowed upon it are sufficient evidences of excellence. As a class journal, devoted to the highest interests of the telegraph profession, it has aimed to be the standard authority, and every effort will continue to be made to maintain this position. Illustrated articles of great value and interest to both professional and non-professional readers have been regularly given, and this feature will be continued in the coming volume. The Answers to Correspondents in each issue is not the least interesting feature of the JOURNAL. Information of much value to the telegraphist has, in this manner, been conveyed, to the manifest improvement of the service.

The JOURNAL began existence with eight pages and a circulation of about three thousand. It was not established with the view of making a profit from its publication, but to provide a vehicle of communication between the officers of the Western Union Telegraph Company and their employés. Hence the terms of subscription and the rates charged for advertising space were placed at figures much below remuneration. These rates have been continued to the present time.

But the JOURNAL of to-day is something very different from the same paper in its inception. Not only has it fulfilled the purpose for which it was established, but it has supplied the want of a first-class paper, devoted to the interest of both the telegraph and its workers. From eight pages it has grown to sixteen, while the circulation has increased from three thousand to nearly eight thousand, and still steadily progresses.

The growth of the business of the telegraph is something marvelous, and seems to be without limit. So the value of a journal keeping pace with this growth, an epitome of every event transpiring in its history, and as a leader and teacher in its progress, cannot be too highly estimated.

The greatly increased expense attending upon the JOURNAL, in its present improved form, no longer allows it to be published at the nominal price heretofore charged. In this view, and with the knowledge of its merit, it has been decided to advance the rate of subscription to two dollars per annum, except to those in the employ of the Western Union Company; to the latter the price for one copy will remain as heretofore, one dollar per annum.

A Telegraph Cable Construction Bill is passing through the New Zealand Parliament. It is intended to promote the laying down of a cable between Australia and New Zealand, and of a duplicate line between Queensland and India.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, December, 6th, 1873.

To all Transfer Agents and Offices:

Applications are constantly received by telegraph at this office from regular transfer offices, for authority to transfer sums in excess of one hundred dollars in order to accommodate customers. Such requests occasion much unnecessary correspondence. It should be generally understood that—

No Transfer Office will be permitted to transfer an amount in excess of the limit prescribed by regulations. Customers should be advised that our rules in this particular are imperative and admit of no exception.

In connection with this subject, the attention of Transfer Agents is called to the fact that inquiries and explanations in regard to transfer orders are made in some instances directly between the offices concerned. This practice is improper and should be discontinued. All correspondence relating to the service must be conducted through the transfer agents. Offices should be instructed to disregard communications received from any other source, and to forward the same by mail to their Transfer Agent.

ADDRESSES.

The following definition of the rules in regard to "addresses" is published for the information and guidance of all concerned.

The address of the payee of a transfer may be, either *the street and number*, or the words "*asking transfer*," "*will call*," or "*address known*," according as circumstances may require.

One of these four forms of address must be used in each case, with this exception: that whenever the address of the payee is given at a Hotel, Post-Office, Bank or other well known public building, the street and number may be omitted.

The same rules will apply in cases where the sender addresses the payee in care of another party ; for example : "Pay John Smith, care Duncan, Sherman & Co., *address known*, New York."

GEO H. MUMFORD, *Vice-Pres't.*

The headquarters of Superintendent Hibbard of the Central Division is at Salt Lake City, Utah, and not at Omaha, Neb. All communications to him should be addressed to the former place.

A letter dated Missouri, presents the following case: "I received a message the other day to the Sheriff of this county. He was not at home, and would not return until the following day. Message was to arrest horse thieves. I saw the thieves pass not long before message was received. If I had made known contents of message, the thieves could have been caught. I said nothing about it. Some say I was wrong in not letting facts be known. Was I right or wrong?"

Answer. You were quite right. Your acting otherwise might have secured the thieves, but it would have violated the sacredness of the telegraph, which is worth much more than the rascals who escaped the clutches of the absent officers.

The acknowledgment of receipts by the Telegraphers' Mutual Benefit Association, will appear in the next issue.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 BROADWAY, NEW YORK,
December 15, 1873.

To all Offices on W. U. Lines:

Managers are requested to send their post-office address, if different from the name of their office, to the Tariff Bureau for publication.

The following changes and additions have been made since the date of the last Circular:

GENERAL INFORMATION.

Clarendon, Ark., closed.
Coloma, Cal., re-opened.
Kingston, Cal., closed.
Firebaugh's Ferry, Cal., re-opened as an other line of tariff, 60 30 from San Juan South ; ck. San Francisco.
Rocklin, Cal., re-opened as an other line office. Tariff 30 10 from Sacramento; ck. San Francisco.
Derby, Conn., closed.
The P. O. A. of Birmingham, Conn., is Derby.
The P. O. A. of Baylis, Ill., is Pineville, Pike Co.; of Gurnee, Ill., P. O. A. is O'Plain, Lake Co.; and of Sheffield, Green Co. Ill., the P. O. A. is Rock Bridge, Green Co.
Sulphur Springs, Ind., closed.
The P. O. A. of Sand Prairie, Iowa, is Vincennes, Lee Co.
Kingsville, Parker, Stranger, and Hartford, Ks., closed.
Rowlandsville, Md , is now a W. U. office, square 67; check direct.
The P. O. A. of Utica Plank, Mich., is Frazer, Macomb Co.
Somerset and Rifle Lumber Boom, Mich, closed.
The notice in relation to Austin, Minn., given in JOURNAL of November first, 1873, is hereby countermanded.
Hereafter, the "Tariff for Other Lines" to Meriden and Waseca will be 100 and 7, and to Madelia, St. James and St. Cloud, Minn., will be 125 and 8 from Chicago, Ill.
Booneville, Miss., re-opened ; square 331.
Bushnell, Neb., closed.
Sidney, Neb., is now an Other Line office. Tariff for Other Lines 65 and 4 from North Platte, Neb., and 65 and 4 from Cheyenne, Wy.
Hereafter the "tariff for Other Lines" to Big Springs, Julesburg and Lodge Pole, Neb., will be 65 and 4 from North Platte Neb., and to Antelope and Potter, Neb., 65 and 4 from Cheyenne, Wy.
Orford, N. H., closed.
Clayton, N. J., re-opened.
Hainesport, N. J., closed.
The P. O. A. of Murray, Orleans Co., N. Y., is Hindsburg, Orleans Co.
Panama, N. Y., changed to Watts' Flats.
Barlow, O., closed.
Centerton, O., closed.
Big Run, O., closed.
Berwick, O., changed to Green Camp.
Frankfort, O., closed.
Newton, O., changed to Broadway.
Petrea, O., closed.
Potter, O., changed to Pottersburg
The P. O. A. of Big Walnut, O., is Taylor's Station, Franklin, O.
Green Springs, O., closed.
Madeira, O., closed.
Raysville, O., closed.
Tresckow, Pa., closed.
Suttons, Pa., changed to Geneva.
Waynesburg Junc., Pa., the office on Other Lines, printed in tariff book, is in Chester Co.
Messages may be taken for Spring City, Chester Co., Pa Send and check business to Royer's Ford, Pa.
Ophir, Utah, re-opened.
Messages addressed to the Navy Yard near Norfolk, Va., should be sent and checked to Portsmouth, Va.
Windom, Wis.—no office at this point.
Fort Sanders and South Pass, Wy., closed.

NEW OFFICES.

286 Shorter's Station, Ala.
401 Jacksonville, Ark.
401 Kensett, Ark.
196 Crawfordsville, Ga.
217 Social Circle, Ga.
347 Decatur Junction, Ill.
525 Garfield, Ks.
465 Severance, Ks.
84 White Fish Point, Mich., P. O. A., Sault St. Marie.

Tariff to square 34, in the northern part of Michigan, will be as follows : $1 from offices in squares 127 and 128 ; $1.50 from offices whose rate to square 127 is 40, 50, or 75 cents ; $2 from

offices whose rate to square 127 is $1 or $1.25; and $2.25 from offices whose rate to 127 is $1.50. It must be understood, however, that offices having a State rate to Michigan will use it on messages to offices in square 34.

Half-rate messages will not be taken for, or received from, Sault St. Marie and white Fish Point, Mich.

To "*Half Rate offices*," on and after December 15th, 1873, night messages may be taken for, and received from, Jacksonville, Palatka, and St. Augustine, Fla., at half-rates for W. U. lines, to and from Lake City, and full rates for "Other Lines" beyond Lake City, Fla.

CUBA CABLE BUSINESS.

We are notified that communication by telegraph is now established between Aspinwall and Panama. Tariff, in addition to the rate to Aspinwall, is one dollar, gold, for ten words, and five cents for each additional word.

WILLIAM ORTON, *President.*

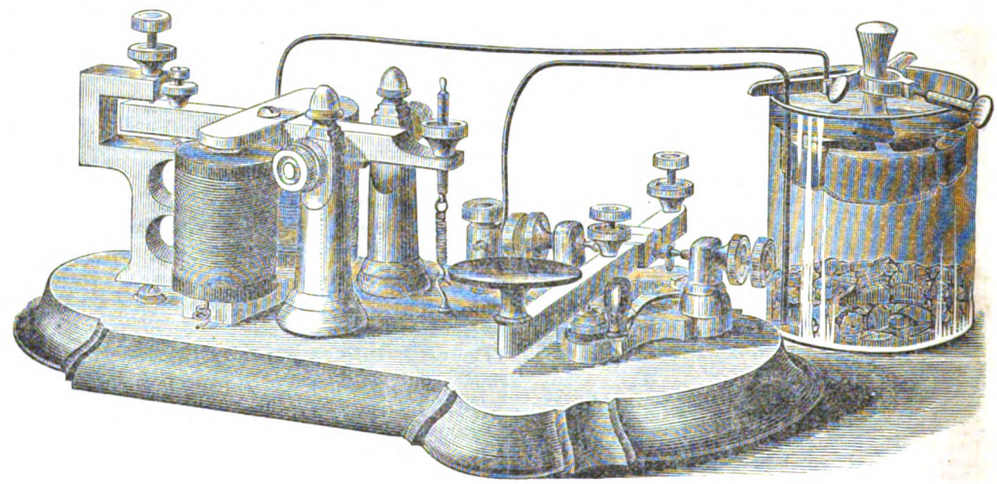
Postmaster Burt, of Boston, recently gave a lecture on the postal service in that city, and illustrated the proverbial carelessness of letter-writers by showing his audience two hundred letters, taken in the office the previous day, which were not properly prepaid or directed, and two hundred and fifty postal cards with all sorts of messages on the face, but not a sign of a direction on the back.

THE Western Union Telegraph Company accomplished the truly marvelous task of transmitting the Message, containing about ten thousand words, in two hours and a half. Unfortunately, we were unable to keep pace with it in setting it up, and, consequently, could only reach one of the evening trains. In order, however, to give this very important document an early circulation, we employed private conveyances to take it to the towns immediately surrounding us, so that the citizens of Pottsville, Palo Alto, Port Carbon, St. Clair, Mt. Carbon, Schuylkill Haven and Minersville were afforded an opportunity before going to rest for the night. We print on our first page to-day the full text of the document, thus insuring the receipt by all of our friends of the President's message to the Forty-third Congress.—*Pottsville (Pa.) Standard.*

Mr. Q. A. STEPHENSON has resigned his position as Superintendent of Telegraph and Train Master on the Peoria, Pekin and Jacksonville Railroad, and will engage in private business.

INJURY TO TELEGRAPH WIRES IN CANADA.—A gale of wind of unusual severity prevailed on the lake coast of Canada on the 4th instant. The telegraph lines in the vicinity of Toronto suffered to a great extent, communication West and North from that city being entirely suspended.

BORN.



FINNON.—At White Hill, New Jersey, Nov. 19, 1873, to Mr. James Finnon, lineman, Amboy Division, a daughter.

DIED.

BINGHAM.—In Lewes, Del., on night of the 12th inst., from chronic dysentery, Ella Elizabeth, youngest daughter of Wm. E. and Anna E. Bingham, aged 16 months and 22 days.

LARISH.—At Buffalo, N. Y., Nov. 27, 1873, Mary E. Bonney, wife of Jos. W. Larish, of the W. U. Tel. Office.

WOODARD.—At Waterford, Pa., Nov. 20, 1873, Morse Whitney, son of Anson H. and Emma A. Woodard, aged 11 months and 4 days.

PARTRICK, BUNNELL & CO.'S

Champion Learners' Instruments.

COMBINED No. 1 SOUNDER AND KEY, with
BATTERY, OFFICE WIRE, CHEMICALS, and a thorough
BOOK of PRACTICAL INSTRUCTION in the Art of Telegraphy

Which latter gives all necessary directions for setting up the Battery and complete apparatus, and operating them for practising or communicating purposes.

THIS IS WARRANTED TO BE, BEYOND ALL COMPARISON, THE BEST APPARATUS EVER OFFERED FOR THE USE OF STUDENTS OF TELEGRAPHY.

Being excellent Morse instruments, substantially made and nicely finished, with nothing left out of their construction which pertains to a Complete Sounder and Key Combination Set. Nothing made in miniature, or in awkward and unusual shape, as is done with the very cheap affairs usually offered as Learners' Apparatus. They are equally well suited

For TELEGRAPHIC SCHOOLS OF INSTRUCTION, For PRIVATE TELEGRAPH LINES, and
For CITY WIRES OF TELEGRAPH COMPANIES.

The BATTERY which accompanies the Learners' Outfit is a full-sized Callaud, the same as the best cells used by Telegraph Companies for main battery, and gives sufficient power to produce a loud, clear sound from the instrument, the Sounder of which embodies the same remarkable principles of sound which have made our "Giant Sounders" so famous and popular among telegraphers.

The BOOK OF INSTRUCTION is a clear and practical explanation, by an experienced telegrapher, of every fact and principle of modern telegraphy and its apparatus which a student of the art could possibly require to obtain, in undertaking to become an accomplished sound operator.

PRICE OF APPARATUS complete, with Book of Instructions, Battery, Wire, and all necessary materials for one complete office outfit, ready for shipment, $10, sent by Express, C. O. D.; or $9.50, if money order for that amount be sent in advance. The latter plan will additionally save the purchaser the Express charges for returning money.

Tickets will be sold here at lowest rates, good from Antwerp and Liverpool to all interior points in the United States, *via* the Pennsylvania Railroad and its connections, thus affording parties in this country a convenient and cheap opportunity of sending for their friends in Europe.

THE RED STAR LINE will give special attention to the comfort of steerage passengers; comfortable berths, well-ventilated sleeping apartments and good food will be furnished them.

An experienced Surgeon is attached to each vessel.

Freight will be received at all principal points in the West and South, in connection with the Pennsylvania Railroad, Southern Mail Steam-ship Company and Clyde's lines, and through Bills of Lading issued for Antwerp, Bremen, Hamburg, Havre, Amsterdam, Rotterdam, Liverpool, London, Glasgow, Belfast, Hull and Leith.

The Red Star Line docks at Philadelphia are in direct connection with the Pennsylvania Railroad, and all merchandise intended for points beyond Philadelphia can be transferred from the hold of the steamer to the cars without the expense to shippers and risk of damage by re-handling, which results from cartage.

For rates of freight and passage, and other information, apply to

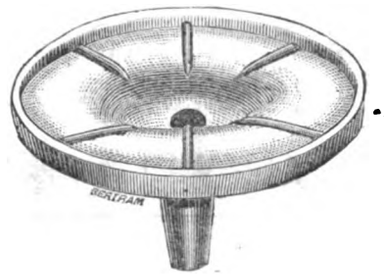
WATTS & COMPANY,

47 Holliday Street,
Baltimore, Md.,

SOLE MANUFACTURERS OF THE

PATENT CIRCUIT-CLOSER KEY,

Which has met with marked success.



Price, $5 50 plain; $7 nickel-plated.

The following is from a competent judge, written after some weeks' trial.

145 BROADWAY, NEW YORK, Sept. 22d, 1873.

DEAR SIR,—Your circuit-closing attachment on the key, left with me for trial, is pronounced by all who have used it a decided and much-needed improvement on the common form.

Respectfully,
A. S. BROWN, *Manager.*

The Best Form of Battery Insulator Offered.

SIMPLE AND PERFECT.

Made of porcelain, handsome in appearance. Occupies little more space than the cell it supports. Each cell of battery completely isolated. Leakage is reduced to the minimum by the use of it.

General Superintendent Van Horn, Southern Division W. U. Tel. Co., writes of it:

"We have now in use a thousand or fifteen hundred of your battery insulators, and expect to order many more before the close of the year.

We have never used any battery insulator that equals it in any respect. In fact, it appears to be as near perfect as we can reasonably expect, in a contrivance for that purpose."

Price 40 cents

We offer a very excellent article of Galvanized Wire, superior to any in the market. The linemen on Baltimore and Ohio R. R. say they have never seen its equal for toughness and flexibility.

Special attention given to building.

Estimates given for any amount of material for telegraph construction or extension.

SWITCHES, GALVANOMETERS, RESISTANCE COILS, &c., to order.

Designs for Switch Boards for special service furnished.

SCOTT'S PATENT ANNUNCIATOR.

for Hotels and Residences.

Security Message Hook.

PATENT APPLIED FOR.

The damage from the loss of a single message will equip a line many times with our new Hook, which gives great security.

Price 30 cents each.

Price per dozen $3.00.

LIBERAL TERMS TO THE TRADE.

MANUFACTURE

Telegraph and Electrical Instruments

OF EVERY DESCRIPTION.

Facilities for supplying any description of Machinery or Material equal to any in the United States.

Patented Dec 31, 1872.

Over SIX THOUSAND cells of the Baltimore Battery in use by the Gold and Stock Telegraph Company of New York in their Private Line Department, is a sufficient acknowledgement of its merit, as a form of the gravity battery, combining the valuable principles of

Economy, Cleanliness and Constancy,

"—in fact a base-burner."

F. L. POPE
Telegrapher, July 5th, '73.

SELF-FEEDING,

No Sulphate of Copper can reach the Sulphate of Zinc Solution.

The shape of Zinc and Copper, which, with the tube, were patented December 31st, 1872, secures the largest surface with least weight of the metals. Half pound sulphate copper per month, ample supply for No. 2, or 3.

Following is one of the many letters we have from reliable telegraphers:

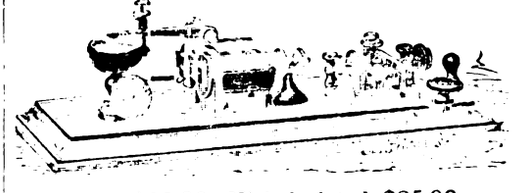
PIEDMONT, W. Va., September 28th, 1873.

Messrs. WATTS & Co.,
Baltimore, Md.

GENTLEMEN:—On January 1st, 1873, I put up 75 cells of your No. 2, Baltimore Battery, in place of 40 cells of carbon, from which two railroad wires of 100 miles each, are supplied. It has not since been taken down or cleaned, and has required no attention, except to fill the tubes with blue stone, once each month, and replenish the fluid once or twice during this period, made necessary by evaporation.

I am fully convinced, from long experience, that this is superior to any other form of the gravity battery.

It has now been in constant use for nine months, and will not need new zinc until after January next.



Respectfully,
J. G. NESBITT, *Manager.*

ORDERS FOR THIS BATTERY PROMPTLY FILLED.

A large stock constantly on hand.

No. 1 for Electro-motors, R. R. signals or similar service,	$2.25
No. 2 ordinary local or Printing Telegraph main	$1.75
No. 3 ordinary main	$1.25

Tillotson's Programme

FOR THE HOLIDAYS.

Attention, Telegraphers!!

In order that we may be able to keep our men employed during the present hard times, we offer the following liberal inducements to purchasers of telegraph material until the

First of January, 1874.

To any person sending us an order for telegraph goods, however small, we will present a copy of Smith's Manual of Telegraphy, gratis.

For an order amounting to from five to ten dollars, we will present one year's subscription to the JOURNAL OF THE TELEGRAPH, or one copy Bond's Hand-book of Telegraph, (British).

For an order amounting to from twenty to thirty dollars, one year's subscription to the Telegrapher, a copy of Pope's Modern Practice of Electric Telegraph, or PRESCOTT'S HISTORY OF THE TELEGRAPH.

For an order amounting to from thirty to fifty dollars, one of either of the following instruments, viz: our Patent Excelsior Instruments for Students' use, our No. 1 or No. 2, Pony Sounder, or our No. 1 or No. 2 Key.

For an order amounting to one hundred dollars, our No. 1, or other style Relay of our manufacture.

For an order amounting to five hundred dollars, our Premium Spring Register.

For an order amounting to one thousand dollars, our Premium Spring Register with No. 1 Relay, Key, Lightning Arrester, and Cut Out, all nickle-plated and combined on marble base.

For an order amounting to ten thousand dollars, our magnificent Set of Sterling Silver Instruments, including Register, Relay and Key, and two Paper Rules, the whole worth $2,000.

Tillotson's Great Specialties.

Johnston's Celebrated Galvanized Line Wire, all sizes, sold at same prices as inferior wire of other manufacture.

The Kenosha Insulators, for which we are the sole Eastern Agents.

The Patent Canvel Screw Glass Insulator.

The New Patent Lockwood Battery.

The Famous Patent Leclanche Battery, for open circuits.

The well-known Patent Hill Battery.

The popular Callaud Battery.

The Patent Nitro-Chromic Battery, for heavy work.

The American Compound Patent Line Wire.

The Bishop Cables, Gutta Percha, Office and Magnet Wires, etc.

The Patent Excelsior Instrument for Amateurs and Students, acknowledged by all to excel any instrument ever designed for this purpose. Its price, its usefulness, its success,—all commend it. It is no toy, but is adapted for circuits of from one to ten miles in length, as well as a mere office circuit

The Patent Jones Lock Switch.

Rhumkorff Coils and Geissler Tubes, etc.

The Premium Spring Register.

The celebrated Relay Magnets, from their peculiar construction, continue to receive the encomiums from Telegraphers to which they are justly entitled.

Our Sounders, Keys and other Machinery are not excelled.

Carbon, Grove, Smee and other Batteries always in stock.
